

Abstract

A guide to the use of natural scientific preserves, Research Natural Areas, on Federal lands in Oregon and Washington. Detailed descriptions of physical and biological features, maps, and photographs are provided for each of the 45 tracts presently reserved. Indices to Research Natural Areas by vegetation type and plant and mammalian species are included.

Keywords: Research Natural Areas, scientific reserves, natural ecosystems, Oregon, Washington.

THE AUTHORS

Dr. Franklin and Dr. Dyrness are Principal Plant Ecologist and Principal Soil Scientist, respectively, at the Forestry Sciences Laboratory, Pacific Northwest Forest and Range Experiment Station, Forest Service, U.S. Department of Agriculture, Corvallis, Oregon; Dr. Hall is Ecologist, Region 6, Forest Service, U.S. Department of Agriculture, Portland, Oregon; and Mr. Maser is Research Associate, Museum of Natural History, University of Puget Sound, Tacoma, Washington. Drs. Arthur R. Tiedemann, Glen O. Klock, and Herbert W. Berndt, scientists at the Forest Hydrology Laboratory, Pacific Northwest Forest and Range Experiment Station, Forest Service, U.S. Department of Agriculture, Wenatchee, Washington, contributed to the description of the Meeks Table Research Natural Area. Dr. William H. Rickard, Jr., Research Ecologist at Battelle Memorial Institute, Pacific Northwest Laboratories, Richland, Washington, provided the description of the Rattlesnake Hills Research Natural Area.

Cooperators in the Federal Research Natural Area Program in Oregon and Washington are:

U.S. DEPARTMENT OF AGRICULTURE
Forest Service

U.S. DEPARTMENT OF THE INTERIOR
Bureau of Land Management
Bureau of Sport Fisheries and Wildlife

FEDERAL RESEARCH NATURAL AREAS IN OREGON AND WASHINGTON:

A Guidebook for Scientists and Educators

Since 1927 Federal land management agencies have been actively developing a system of Research Natural Areas on federally owned lands. On these areas, plant communities and other natural features are preserved for scientific and educational purposes. This natural area system offers biologists and other natural scientists unique opportunities to study biota, environments, and ecological processes in unmodified conditions with a minimum of interference to their work.

In the Pacific Northwest there are 48 of these Research Natural Areas covering about 49,000 ha. (115,000 acres)¹, each administered by one of five cooperating agencies: Forest Service in the U.S. Department of Agriculture; Bureau of Land Management, Bureau of Sport Fisheries and Wildlife, and the National Park Service in the U.S. Department of Interior; and the Atomic Energy Commission. The physical, biological, and historical features of these 48 areas are the subjects of this guidebook. Regulations covering their protection and scientific and educational use are also outlined. Our purpose is to make these areas and their research potential known to the scientific community and thereby stimulate their use for research. We also hope to make the scope and purposes of the Federal Research Natural Areas better known.

The guidebook is divided into two major sections. Part I concerns the purposes of Research Natural Areas, agency guidelines for management and protection, and the obligations and opportunities for scientist users. Part II provides individual descriptions for each of the established Research Natural

Areas in Oregon and Washington.² Various indices to the Research Natural Areas and examples of Federal agency regulations concerning them are provided in appendices.

PART I. MANAGEMENT AND USE OF FEDERAL RESEARCH NATURAL AREAS

Research Natural Area is a classification utilized by the Federal land management agencies to designate lands on which various natural features are preserved in an undisturbed state solely for research and educational purposes. The specificity of this designation and the regulations controlling the use of Research Natural Areas set them apart from other land classifications having recreational, wilderness, and similar orientations which, although they may incorporate preservation of natural features of scientific interest, do not have this as their exclusive focus.

In the United States many agencies, primarily in the Departments of Agriculture and Interior, are cooperating in development of an adequate nationwide system of these scientific reserves. A recent directory indicates the extent of these activities.³

¹ A single tract, the Rattlesnake Hills Research Natural Area of the Atomic Energy Commission, comprises about 33,000 ha. or 75,000 acres of this total. The remaining 47 areas cover about 16,000 ha. or 40,000 acres.

² Descriptions of the three most recently established areas, Bagby, Lost Forest, and Wheeler Creek Research Natural Areas, will be issued as supplements. They have been included in the various tables and indices, however.

³ Federal Committee on Research Natural Areas. A directory of Research Natural Areas on Federal lands of the United States of America. Washington, D.C., Superintendent of Documents, 129 p., 1968.

Purposes of Research Natural Areas

Research Natural Areas are tracts where natural processes are allowed to dominate and where some natural feature(s) is preserved for research and education. The main reasons for preserving these tracts can be summarized as follows:

1. To provide baseline areas against which the effects of human activities in similar environments can be measured;
2. To provide sites for study of natural processes in undisturbed ecosystems; and
3. To provide gene pool preserves for plant and animal species, particularly of rare and endangered types.

A more detailed discussion on the kinds and importance of research possible in Research Natural Areas is found in Franklin and Trappe.⁴

Many kinds of natural features, biological and physical, are protected within Research Natural Areas. As originally conceived by scientists in the Forest Service, Society of American Foresters, and Ecological Society of America, natural areas were tracts of land set aside to preserve examples of important plant communities, i.e., major forest and range types. The concept has been rapidly expanded in recent years to incorporate unique communities and community mosaics, aquatic as well as terrestrial. Physical features such as unique geological formations or type localities for certain kinds of soils are also eligible for Research Natural Area designation. This inclusive concept of features suitable for recognition⁵ requires only that the natural feature be primarily of scientific and educational value and that the restrictive Research Natural Area designation is necessary or desirable for its protection. However, all of the existing tracts in the Pacific Northwest have been set aside with plant communities as the focal point of interest and

⁴ Jerry F. Franklin and James M. Trappe. Natural areas: needs, concepts, and criteria. *J. For.* 66: 456-461, illus., 1968.

⁵ See footnote 3.

fauna and physical features protected only coincidentally.

Management of Research Natural Areas

All involved agencies have developed similar sets of regulations to insure that protection of the scientific and educational values of Research Natural Area tracts dominates their management and use. The Federal Committee on Research Natural Areas is presently attempting to develop a standard set of regulations. We base the following discussion on U.S. Forest Service regulations, which are reproduced in Appendix I; the other agencies have similar if not identical policies.

The guiding principle is to prevent unnatural encroachments, activities which directly or indirectly modify ecological processes on the area. Logging activities including salvage of dead or diseased trees are prohibited. Uncontrolled grazing by domestic livestock is not allowed, and while controlled grazing is still practiced on a few Forest Service and Bureau of Land Management areas, it will ultimately be continued only where it is used as a manipulative treatment for maintenance of some natural feature(s) of interest. Physical improvements such as roads, trails, fences, and buildings are generally not allowed except those considered essential to proper research or educational use of the area. Wildfires are extinguished as quickly as possible, but no postfire activities such as fire hazard reduction or reforestation are allowed. Similarly, insect or disease control programs are not carried out except where the infestation threatens adjacent forest or will drastically alter natural ecological processes within the tract.

Public uses which might contribute to significant modification of Research Natural Areas are generally discouraged, and some agencies provide expressly for prohibition of such use if serious impairment of scientific or educational values is threatened. This includes such activities as picnicking, camping, and gathering plants, nuts, and berries.

Hunting, fishing, and trapping of fur-bearing animals is typically permitted subject only to State regulations except on lands within National Parks. More stringent controls over animal removal will certainly be developed as faunal aspects of Research Natural Areas receive attention more comparable to that afforded the botanical aspects. None of the agencies have purposely encouraged public use of Research Natural Areas through publicity and recreational developments. However, some peripheral nature trails and interpretive signs have been proposed or established, and more can be expected in the future as part of intensified management plans to control public use and protect these increasingly conspicuous undisturbed landscapes.

All agencies provide for management practices necessary to preserve some representation of the plant community for which the Research Natural Area was originally created. Such treatments might include controlled burning to preserve a seral, fire type or controlled removal of excess animal populations. In fact, no such treatments have been applied to Research Natural Areas in the Pacific Northwest. Controlled burning to preserve portions of a prairie tract is the only significant treatment contemplated in the near future. Management practices of this type are to be applied only where they provide a closer approximation of the vegetation and governing processes than would otherwise be possible. Furthermore, suitability of the techniques must be determined by research and testing prior to their application, and a portion of the tract is to be kept as an untreated control.

Use of Research Natural Areas for Scientific Purposes

Federal Research Natural Areas provide a uniquely valuable system of field sites for research and education in the natural sciences. Here are publicly owned and protected examples of undisturbed ecosystems made available

to the scientist. He can conduct his research with minimal interference and reasonable assurance that investments in long-term studies will not be lost to logging, land development, or similar activities. Valuable inputs from other scientific disciplines can be expected as other studies are conducted on the area and a body of knowledge on its natural features accumulates.

In return, the scientist wishing to use a Research Natural Area has some obligations. He must:

1. Obtain permission from the appropriate administering agency before using the area;
2. Abide by the administering agency's regulations governing the use of the natural area including specific limitations on the type of research, sampling methods, etc., allowed; and
3. Inform the administering agency on the progress of the research, published results, and disposition of collected materials.

The purposes of these limitations are simple — to insure that the scientific and educational values on the tract are not impaired, to accumulate a documented body of knowledge about the tract, and to avoid conflict between new and old studies.

LIMITATIONS ON RESEARCH AND EDUCATIONAL USE

Use of Research Natural Areas by responsible scientists and educators is encouraged; however, this use must be consistent with protection of the features for which the tract was set aside. The limitations on use will, of course, vary with the particular tract and the specific features of interest. Many of the natural areas in the Pacific Northwest are large, rugged, forested areas. They can tolerate considerably heavier use (e.g., more soil pits, larger student parties) than is likely in the foreseeable future. Some entire Research Natural Areas and portions of many others are extremely fragile, however, and use must be carefully controlled and disturbances

minimized. Bogs and some meadow communities are of this type.

In general, educational use should be at the upper classman or graduate college level. Some care is required even within these restrictions where large groups of students or particularly fragile natural features are involved. For example, students once made aware of a tract could return and seriously affect biological populations by their collecting.

Research on Research Natural Areas must be essentially nondestructive in character. Felling trees for biomass or tree ring analysis is generally not allowed. Neither are manipulative type studies requiring extensive forest floor modification or extensive soil excavation. Collection of plant and animal specimens should be restricted to the minimum necessary for provision of vouchers and other research needs and in no case to a degree which significantly reduces species population levels. Of course, such collections must also be carried out in accordance with applicable State and Federal agency regulations.

Within these broad guidelines, the appropriate uses of Research Natural Areas are determined on a case-by-case basis by the administering agency. The procedure by which the scientist or educator obtains permission to use the areas is outlined in the following section.

OBTAINING PERMISSION TO USE RESEARCH NATURAL AREAS

A scientist wishing to use a particular Research Natural Area must determine the administering agency (since there is no single administering authority), contact it regarding the proposed use, and obtain the necessary permission. Each agency differs slightly in its requirements.

Forest Service. — Research Natural Areas are located within Ranger Districts which are themselves administrative subdivisions of National Forests. Normal management and protective activities are the responsibility of District Rangers and Forest Supervisors who direct these organizational units. However,

scientific and educational uses made of Forest Service Research Natural Areas are a responsibility of the research branch of that organization. Therefore, a scientist interested in using one of these tracts in Oregon and Washington should contact the Director of the Pacific Northwest Forest and Range Experiment Station (P.O. Box 3141, Portland, Oregon 97208) and outline the activity he plans. If extensive use of one or more Forest Service Research Natural Areas is planned, a brief cooperative agreement between the scientist and the Forest Service may be necessary to protect the investigator's work and the character of the natural areas.

The Forest Supervisor and District Ranger administering the affected Research Natural Area will be informed of mutually agreed upon activities by the Experiment Station Director. However, a scientist should still visit the administering ranger station when beginning his studies and explain the nature, purpose, and duration of his activities. Permission for brief visits to Research Natural Areas for observational purposes can be obtained from the District Ranger.

Bureau of Land Management. — Bureau of Land Management Research Natural Areas are administered by District Offices which are organizational subdivisions of the State offices. Scientists wishing to use these Research Natural Areas should contact the Bureau's State Director. At present, all of this agency's tracts are located in Oregon so the responsible individual is the Oregon State Director (Bureau of Land Management, P.O. Box 2965, Portland, Oregon 97208). The manager of the district in which the Research Natural Area is located will be informed of mutually agreed upon activities by the State Director. Nevertheless, a scientist should visit the administering district office when beginning his studies and explain the nature, purpose, and duration of his activities if at all possible. Permission for brief observational visits to Research Natural Areas can be obtained from District Managers.

Bureau of Sport Fisheries and Wildlife. — The Bureau's Research Natural Areas are all located on National Wildlife Refuges and the

Refuge Manager is the administering officer. The Bureau has established formal procedures for conduct of research activities on its lands. A scientist wishing to use one of the areas must contact the Refuge Manager involved and outline his study proposal. A written agreement is required.

National Park Service. — National Park Service Research Natural Areas are located within National Parks or Monuments which are administered by Superintendents. A scientist wishing to use one of these tracts should first contact the Superintendent responsible for the Park in which the Research Natural Area is located and outline his proposed research. Because of their long involvement with scientific and educational use of the National Parks and Monuments, the National Park Service has developed some standard procedures covering applications for such uses.

Eventually all research must be approved by the area Superintendent, Director of the Region, and Chief Scientist. A resources study proposal must be prepared by the principal investigators for the above administrators' review and approval; area research biologists will assist in preparation of the proposal. Formal collecting permits are necessary within Research Natural Areas as well as the Parks in general. There may be limitations on research activities located on Research Natural Areas within designated wilderness areas. Prospective researchers may find useful "Administrative Policies for Natural Areas of the National Park System," of the National Park Service.

Atomic Energy Commission. — The Atomic Energy Commission's Rattlesnake Hills Research Natural Area is located on the Commission's Hanford Works Reservation. Research on this tract is managed by the Battelle Memorial Institute's Pacific Northwest Laboratories. A scientist wishing to use this tract should contact Dr. Burton E. Vaughn, Manager, Ecosystems Department, Battelle-Northwest, Richland, Washington 99352.

Future Development of the Research Natural Area System

The Pacific Northwest has a very fine series of Research Natural Areas, but the Federal agencies involved feel it is still far from complete. Areas are systematically being sought to provide needed representation of major forest and range communities as well as additional areas for rare and endangered species and aquatic ecosystems. An average of two new Research Natural Areas is being added each year.

This work is a cooperative effort between the Forest Service, Bureau of Land Management, Bureau of Sport Fisheries and Wildlife, National Park Service, and Atomic Energy Commission and is carried on with the encouragement of the Federal Committee on Research Natural Areas. The Pacific Northwest Research Natural Area Committee is a focal point for much of the activity and initiated and coordinated preparation of this guidebook. This committee is chaired by the Director of the Pacific Northwest Forest and Range Experiment Station.

Scientists are encouraged to share their comments and opinions on the Federal Research Natural Area program with either the local or national committees. Suggestions of community types requiring additional protection or of areas suitable for designation are also desired.

PART II. FEDERAL RESEARCH NATURAL AREAS IN OREGON AND WASHINGTON

There are presently 48 established Research Natural Areas on Federal lands in Oregon and Washington (table 1) covering a wide range of biotic communities and geographic area (fig. 1). The following section of this

guidebook provides generalized descriptions of each of these tracts. Each description is individually paged to allow easy insertion of descriptions of new areas or revised descriptive materials for the areas already included. The Research Natural Areas are presented in alphabetical order; table 1 provides the key to the pagination as well as indicating the principal features and administering agency for each tract. Indices to the natural areas by vegetation type, important forest and range species, and animals are provided in appendices.

Scientists using the guidebook should recognize that the biological and environmental descriptions are based on very limited information. In most cases they are based on a 1- or 2-day reconnaissance supplemented by data from the establishment report. Plant communities, floras, or faunas have not been systematically surveyed on any of the areas at this time; quantitative studies or extensive collections are also generally lacking. Climatic and geologic descriptions are based on the best published references covering these areas and generally not on onsite field studies. Tentative lists of mammals expected as residents or transients have been prepared by Mr. Maser for most Research Natural Areas

based upon the habitat descriptions and known species ranges. These lists will be revised and similar tabulations prepared for birds, reptiles, and amphibians as field data become available.

We have followed a common outline in describing each Research Natural Area: capsule summary; establishment data; size; administering agency; location; environmental, biological, and historical features; history of research; and availability of special maps (geologic, topographic, etc.). Common names have been used for shrubs and herbs which are important range plants and for trees with the scientific name provided after the first usage of the common name. Other plants are cited by their scientific names. Common names are also utilized for animal species when they are available; otherwise scientific names are used. Planimetric or topographic maps of each tract, and occasionally special maps showing the distribution of geology, soil, or vegetation, are included. For a general planimetric map of the Research Natural Area and surrounding lands, scientists should obtain a regular map of the Forest, Park, management district, or wildlife refuge in which it is located from the administering office.

Figure 1. — Geographic distribution of established Federal Research Natural Areas in Oregon and Washington (see table 1 to relate letter code to specific Research Natural Area).

ABBOTT CREEK RESEARCH NATURAL AREA¹

Southwestern Oregon mixed conifer forest with especially fine examples of sugar pine occupying a large (1,077 ha.) mountain stream drainage.

Abbott Creek Research Natural Area was established on November 18, 1946, to exemplify the Sierra-type mixed conifer forests found in southwestern Oregon. The tract was specifically selected because of the excellent representation of sugar pine (*Pinus lambertiana*) in many of the stands. The 1,077-ha. (2,660-acre) natural area is located in Douglas and Jackson Counties, Oregon, and is administered by the Prospect Ranger District (Prospect, Oregon), Rogue River National Forest. It occupies portions of sections 23, 24, 25, 26, and 36, R. 2 E., T. 30 S., and of sections 19, 30, and 31, R. 3 E., T. 30 S., Willamette meridian. The majority of the boundaries follow physiographic features (fig. AC-1): the dividing ridge between the Rogue and Umpqua Rivers on the north, the Golden Stairs trail, which essentially follows a ridgetop on the east, and the main and west branches of Abbott Creek along much of the west edge. The natural area is located at 42°56' N. latitude and 122°31' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is approached via Oregon State Highway 26. Personnel at Prospect

¹ Description prepared by Dr. Jerry F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

Ranger Station can provide directions through the network of graveled forest roads which lead from the highway to the southwestern corner (Forest Road 3047) and eastern edge (Forest Road 3016) of the tract (fig. AC-1). Unimproved dirt roads also lead to Abbott Butte Lookout at the northwestern corner (Forest Road 2923) and along the west side of the main branch of Abbott Creek; the latter road is drivable for only a short distance. The unmaintained Golden Stairs trail forms the western boundary.

Cross-country foot travel provides the only access within the natural area; there are no trails or roads inside the boundaries. Because of its large size and rugged character such travel is time consuming and often difficult and hazardous.

Commercial accommodations are available at Prospect and Union Creek located approximately 16 to 24 km. (10 to 15 miles) from the natural area. There are also numerous improved forest campgrounds in the vicinity.

ENVIRONMENT

The Abbott Creek Research Natural Area is a relatively large mountainous tract which occupies the entire drainage of the main branch of Abbott Creek as well as portions of tributary drainages (fig. AC-1). Topography is generally rugged with moderate to steep slopes and numerous rock outcrops and escarpments. Small benches along Abbott Creek and more extensive benchy areas below the summit peak of Abbott Butte provide the only gentle relief. Elevations range from about 1,000 m. (3,300 ft.) to 1,869 m. (6,131 ft.) at Abbott Butte Lookout.

The natural area is located in the geologically older western Cascades and is composed entirely of volcanic materials. Bedrock at higher elevations is composed of middle and upper Miocene andesite flows, probably belonging to the Sardine formation (Peck 1961).

At lower elevations, Oligocene and lower Miocene pyroclastic rocks occur and may include tuffs, breccias, and conglomerates. The summit area of Abbott Butte itself is mapped as basalt of Pliocene or Pleistocene age. Finally, some Eocene to Pliocene felsic intrusive rocks may occur along the west boundary.

The natural area is subject to a modified maritime climate with cool, wet winters and warm, dry summers. There are strong elevational gradients in temperature, snowfall, and snowpack accumulation. Lower part of the tract is typical of midelevational, montane forest environments in the southern Oregon Cascades while highest elevations are subalpine in character. Climatic data from the Prospect Weather Station located 19 km. (12 miles) southeast of the natural area are as follows (U.S. Weather Bureau 1965):

Mean annual temperature	9.9°C.(49.9°F.)
Mean January temperature	1.9°C.(35.4°F.)
Mean July temperature	19.0°C.(66.2°F.)
Mean January minimum temperature	-3.3°C.(26.1°F.)
Mean July maximum temperature	30.0°C.(86.1°F.)
Average annual precipitation ..	1,059 mm.(41.69 in.)
June through August precipitation	62 mm.(2.43 in.)
Average annual snowfall	161.5 cm.(63.6 in.)

Conditions are wetter and cooler on the natural area, even at lower elevations within it. Isohyetal maps suggest annual precipitation varies from 1,575 to 1,725 mm. (62 to 68 in.) on the natural area (Oregon State Water Resources Board 1959).

Soils in the area have not been mapped or described. Great soil groups present include the Lithosol, Brown Podzol, and Alluvial groups and possibly the Western Brown Forest and Gray-Brown Podzol great soil groups.

BIOTA

Approximately 832 ha. (2,055 acres) of the natural area are forested and 245 ha. (605 acres) are occupied by nonforested communities. In the absence of a detailed type map it is probably best to categorize all of

the forested acreage as SAF forest cover type 243, Ponderosa Pine-Sugar Pine-Douglas-Fir (Society of American Foresters 1954). Although the broadly defined type definition makes this possible, it scarcely does justice to the diversity of forest conditions present on the tract; individual stands are present which fit SAF cover types 211, White Fir; 229, Pacific Douglas-Fir; and 207, Red Fir. Küchler (1964) types represented include 5, Mixed Conifer Forest; 7, Red Fir Forest; 12, Douglas Fir Forest; and 33, Chaparral. The bulk of the natural area lies within the Mixed Conifer Zone of Franklin and Dyrness (1969) although elements of the *Abies concolor* and *Abies magnifica shastensis* Zones are also present at higher elevations.

Major tree species in approximate order of importance are: Douglas-fir (*Pseudotsuga menziesii*), sugar pine, white fir (*Abies concolor*), incense-cedar (*Libocedrus decurrens*), Shasta red fir (*Abies magnifica* var. *shastensis*), western hemlock (*Tsuga heterophylla*), mountain hemlock (*Tsuga mertensiana*), western white pine (*Pinus monticola*), and ponderosa pine (*Pinus ponderosa*). The first four are found over almost the entire area. White fir does tend to increase in dominance in stands at higher elevations (especially above 1,450 to 1,600 m. or 4,750 to 5,250 ft.) and in stream terraces. Shasta red fir and mountain hemlock are generally confined to elevations over 1,600 m. (5,250 ft.). Western hemlock occurs mainly on terraces next to Abbott Creek which is also where western white pine are most common. Ponderosa pine is typical of the warmest, driest habitats such as steep southerly slopes at lower elevations. Minor tree species present include subalpine fir (*Abies lasiocarpa*), bigleaf maple (*Acer macrophyllum*), golden chinkapin (*Castanopsis chrysophylla*), Oregon white oak (*Quercus garryana*), and Pacific yew (*Taxus brevifolia*).

White fir appears to be the major climax tree species in most of the forest stands. Seedlings and saplings of this species are typically more common than reproduction of Douglas-fir or incense-cedar under closed forest canopies. However, most of the stands are in relatively long-lasting seral stages

many decades, or perhaps several centuries, away from climax condition even in the absence of wildfire or other disturbances. Severe environmental conditions on many sites retard successional processes, and there are numerous small openings which allow less shade-tolerant species, such as Douglas-fir, incense-cedar, and sugar pine, to reproduce (fig. AC-2).

The composition of all layers of the forest communities varies markedly with moisture and temperature gradients, which are roughly correlated with soil-land form and elevation, respectively, and with stand history. Mature forests on mid and lower slopes are dominated by a mixed overstory of Douglas-fir, incense-cedar, sugar pine, and white fir. Common understory species include *Corylus cornuta* var. *californica*, *Pachistima myrsinites*, golden chinkapin, *Rosa gymnocarpa*, and *Vaccinium membranaceum* in the shrub layer and *Chimaphila umbellata*, *Achlys triphylla*, *Berberis nervosa*, *Pyrola picta*, *Iris chrysophylla*, *Trientalis latifolia*, and *Carex* sp. in the herb layer. There are many variations on this basic theme, however. For example, incense-cedar and Douglas-fir increase in relative importance and ponderosa pine and a variety of hardy intolerant shrubs and herbs, including many typical of the nonforest communities discussed below, make their appearance in drier phases of this community.

Stands on stream terraces typically have more white fir and less incense-cedar in the overstory. Douglas-fir remains a major dominant. Several species are found solely or in greatest abundance in these terrace communities: western hemlock and western white pine in the tree layer; Pacific yew, vine maple (*Acer circinatum*), and Pacific dogwood (*Cornus nuttallii*) in the shrub layer; and *Asarum caudatum*, *Trillium ovatum*, *Disporum hookeri*, *Clintonia uniflora*, *Viola glabella*, *Linnaea borealis*, *Calypso bulbosa*, *Anemone deltoidea*, *Rubus nivalis*, and *Viola sempervirens* in the herb layer. These species sharply distinguish the terrace communities from those found on more xeric habitats.

Higher elevation forest stands include some dominated by white fir with relatively lush understories of forbs or weeds. Typical under-

story plants are *Ribes viscosissimum*, *Mertensia paniculata*, *Smilacina sessilifolia*, and a variety of other broad-leaved herbs and several grasses. Small stands dominated by Shasta red fir, either pure or in mixture with white fir or mountain hemlock, are also present. These characteristically have sparse understories.

The nonforested communities are also highly variable in character including several rock outcrop types and subalpine mosaics of relatively lush herbaceous stands and tree and shrub patches. Communities on rock outcrops and scree slopes reflect the extremely xeric habitat (fig. AC-2). Typical plant species include *Ceanothus prostratus*, *Arctostaphylos nevadensis*, *Senecio integerrimus* var. *exaltatus*, *Pellaea* sp., *Cheilanthes gracillima*, *Cystopteris fragilis*, *Stipa columbiana*, *Collomia heterophylla*, *Cynoglossum grande*, *Delphinium* spp., *Ribes cereum*, *Marah oreganus*, and *Epilobium minutum*. On some nonforested sites, as well as in open forest stands, there are larger evergreen shrubs such as *Arctostaphylos patula*, *Ceanothus velutinus*, and *Garrya fremonti*.

The meadows at high elevations are dominated by herbaceous species such as *Veratrum viride*, *Pteridium aquilinum*, and various grasses and sedges. Small perennial herbs such as *Erythronium grandiflorum* and *Claytonia lanceolata* are also common. Intermixed with the herbaceous stands are large *Sorbus* bushes and individuals and groups of young trees — incense-cedar, white fir, and Shasta red fir. There has been extensive meadow invasion by tree species during the last century.

Mammals believed to utilize the natural area as residents or transients are listed in Table AC-1. Reptiles and amphibians present probably include spiny lizards (*Sceloporus* spp.), striped skinks (*Eumeces* spp.), garter snakes (*Thamnophis* spp.), frogs (*Rana* spp.), and toads (*Hyla* spp.). A great variety of resident and transient birds utilize the tract including grouse (Phasianidae), hawks (Accipitridae), jays (Corvidae), owls (Columbidae), woodpeckers (Picidae), nuthatches (*Sitta* spp.), wrens (Troglodytidae), and sparrows

3).

streamsides, and springs provide
atic and semiaquatic habitat
st to animal ecologists and
ts. As mentioned, there are
as rock outcrops and cliffs which
sialized habitats.

HISTORY OF DISTURBANCE

The most important human disturbances to the natural area have resulted from grazing and logging; fortunately the tract is large so the overall impact has not been significant. It is estimated that approximately 12 to 16 ha. (30 to 40 acres) of the natural area has been unintentionally clearcut due to inadequate attention to the area's boundaries; this involves a clearcut north of the west branch of Abbott Creek in sections 25 and 26 and the western third of another in section 30. Partial cutting has also taken place along the west edge of the tract in sections 30 and 31 and salvage logging in a small area just inside the boundary in section 19. Trees were marked for salvage cutting within the natural area along the west branch of Abbott Creek but were never cut; however, there is evidence of an earlier light cutting in the same area.

Drifting cattle have grazed the meadows and open forests at higher elevations for many years and still do so every summer. The grazing appears to have significantly altered the composition of meadows and of the understory in some forest stands.

A lookout station has been maintained for many years on top of Abbott Butte but has had no significant impact on the area. The only other human use of the tract is by hikers, hunters, and tourists. This is confined to the edges and has had no influence on natural processes.

Wildfire has undoubtedly been a major influence in creating the present community mosaic. Young stands, brushfields, and fire scars provide abundant evidence for periodic wildfires prior to initiation of fire control

programs about 1910. None are known to have occurred in recent years.

RESEARCH

A study of the plant communities and species with emphasis on classification and environmental relationships is presently underway.² It has also been used as a sampling site in taxonomic studies of variation in the noble - California red fir species complex.³

The tract provides innumerable opportunities for research on southwestern Oregon mixed-conifer forests because of its size and the diversity of stand conditions and environments present. These could include studies of hydrologic and nutrient cycling in an essentially virgin drainage; life histories of all but the largest animals; and variations in composition, productivity, and successional development of plant communities. It is an excellent location for studies of sugar pine growing under near-optimum conditions as well as for ecological studies of many other tree species. The unintentional clearcuts also provide opportunities to study secondary succession.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Abbott Butte, Oregon quadrangle, scale 1:62,500 issued by the U.S. Geological Survey in 1944; and *geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (Prospect Ranger District) or Forest Supervisor (Rogue River National Forest, Medford, Oregon) can provide details on the most recent aerial photo coverage of the area.

² Research by Mr. R. Mitchell, Department of General Science, Oregon State University, Corvallis.

³ Research by Dr. J. F. Franklin, U.S. Forest Service, Forestry Sciences Laboratory, Corvallis, Oregon.

Jackson and Douglas Counties, Oregon.*

Figure AC-2.—Natural features of Abbott Creek Research Natural Area. Upper left: Looking north over the northwestern quarter of the natural area from a rocky promontory in section 31; all the area visible is within the natural area. Upper right: Typical old-growth specimen of sugar pine, a species well represented in the natural area. Center left: Community of *Arctostaphylos nevadensis* and *Ceanothus prostratus* growing on an open scree slope. Lower left: Typical south slope stand of Douglas-fir, incense-cedar, and scattered sugar pine. Lower right: Forest opening occupied by reproduction of Douglas-fir and sugar pine; frequent openings of this type provide sites for reproduction of less shade-tolerant tree species.

ASHLAND RESEARCH NATURAL AREA¹

“Pacific” ponderosa pine and ponderosa pine-Douglas-fir forests in a steep, granitic mountain valley of southwestern Oregon’s Siskiyou Mountains.

The Ashland Research Natural Area was established on May 4, 1970, to provide examples of the “Pacific” ponderosa pine (*Pinus ponderosa*) and ponderosa pine-Douglas-fir (*Pseudotsuga menziesii*) forests found west of the Cascade Range in southern Oregon. The 570-ha. (1,408-acre) tract is located in Jackson County and is administered by the Ashland Ranger District (Ashland, Oregon), Rogue River National Forest. The natural area occupies portions of sections 21, 27, 28, 33, and 34, T. 39 S., R. 1 E., and sections 3, 4, 9, and 10, T. 40 S., R. 1 E., Willamette meridian. About three-fourths of the tract is bounded by roads: Forest Roads 3963 and 3903 on the east and south and Forest Road 3903-B (a spur) on the southwest (fig. AS-1). Ridgetops form most of the remaining northeast and east boundary. The natural area lies at 42°08' N. latitude and 122°43' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area will normally be reached from Ashland, located about 5 km. (3 miles) to the north, via either Forest Road 3963 or 3903. These roads are located on the upper edge of the natural area and provide general views and access. The lower edge of the

natural area can be reached via Forest Road 3925 which goes past Reeder Reservoir; however, this road is blocked by a locked gate.

There are no maintained trails within the natural area. The steep, broken topography and brush make cross-country travel somewhat arduous and hazardous. There is an old trail which crosses the northern part of the natural area from east to west (fig. AS-1).

Numerous commercial accommodations are available at Ashland.

ENVIRONMENT

The natural area occupies the slopes of a rugged mountain canyon along the East Fork of Ashland Creek. Topography is steep to very steep throughout most of the tract, with many spur ridges and subdrainages occurring at right angles to the main drainage. Areas of gentle to moderate slopes are found in southern and southwestern portions of the natural area. Elevations range from about 840 m. (2,800 ft.) at Reeder Reservoir to a maximum of about 1,400 m. (4,600 ft.).

The natural area is located on intrusive granitoid rocks of upper Jurassic and lower Cretaceous age (Wells 1956). Quartz diorite, a light- to medium-gray rock of sodic plagioclase and quartz, dominates. It may contain minor amounts of hornblende or biotite or both.

The climate is typical of inland valleys in southwestern Oregon. Summers are warm and dry, and winters are cool and moist. Extended summer drought periods are common. Some winter precipitation occurs as snow, the percentage of snow and total precipitation increasing rapidly with elevation. The following climatic data from Ashland (located at about 610-m. or 2,000-ft. elevation, 5 miles or 3 km. to the north) are reasonably representative of conditions in the lower part of the natural area (U.S. Weather Bureau 1965):

¹Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

Mean annual temperature 11.3°C. (52.4°F.)
Mean January temperature 3.6°C. (37.5°F.)
Mean July temperature 20.6°C. (69.1°F.)
Mean January minimum temperature . -0.5°C. (30.1°F.)
Mean July maximum temperature . . 30.2°C. (86.4°F.)
Average annual precipitation 508 mm. (19.99 in.)
June through August
precipitation 46 mm. (1.81 in.)
Average annual snowfall 39 cm. (15.3 in.)

Soils within the natural area are typically relatively shallow and coarse-textured. The major soil series present is probably the Siskiyou series, a type of Grey Brown Podzol, with a thin A1 horizon and yellowish-brown B2.

BIOTA

Approximate areas by SAF forest cover type are as follows (Society of American Foresters 1954):

No.	Name	Area
245	Pacific Ponderosa Pine	152 ha. (375 acres)
244	Pacific Ponderosa Pine-Douglas-Fir	292 ha. (720 acres)
229	Pacific Douglas-Fir	113 ha. (280 acres)
234	Oak-Madrone	8 ha. (21 acres)
243	Ponderosa Pine-Sugar Pine-Douglas-Fir	3 ha. (12 acres)

As will be seen, assignment of many stands to these categories is necessarily somewhat arbitrary. Küchler (1964) types represented probably include 10 (Ponderosa Shrub Forest), 5 (Mixed Conifer Forest), 12 (Douglas Fir Forest), and 29 (California Mixed Evergreen Forest). The natural area appears to lie primarily within the southwestern Oregon Mixed Conifer Zone (Franklin and Dyrness 1969), although elements of the *Abies concolor* and Interior Valley Zones are present at highest and lowest elevations, respectively.

It is important to note that the natural area is located in the eastern Siskiyou Mountains, an area impoverished in species in comparison with either the western Siskiyou Mountains or southern Cascade Range (Waring 1969). Furthermore, the natural area occupies an area where strong environmental gradients, particularly of temperature and moisture, have been demonstrated and quantified (Waring 1969). These have profound

effects on community composition and make it difficult to break the mosaic into community types.

Common tree species within the natural area include ponderosa pine, Douglas-fir, sugar pine (*Pinus lambertiana*), white fir (*Abies concolor*), and Pacific madrone (*Arbutus menziesii*). Less important species include California black oak (*Quercus kelloggii*), Oregon white oak (*Quercus garryana*), chinquapin (*Castanopsis chrysophylla*), and incense-cedar (*Libocedrus decurrens*). Bigleaf maple (*Acer macrophyllum*), white alder (*Alnus rhombifolia*), Pacific yew (*Taxus brevifolia*), and vine maple (*Acer circinatum*) are found along the stream bottoms.

The major climax species appear to be Douglas-fir and white fir. Douglas-fir is probably the typical climax tree on warmer and drier sites such as are found at lower elevations and southerly-exposed slopes. Ponderosa pine is probably not climax anywhere in the natural area, even where Douglas-fir is presently absent.² However, successional processes are often slow on these sites due to the severe microclimate and historically open nature of the stands. White fir is clearly the major climax species at higher elevations and on moister habitats; this is certainly the case where it presently occurs and is probably so in some other stands where this fire-sensitive species does not yet occur.

The forest stands classed as "Pacific Ponderosa Pine" are generally found in the lower third of the natural area (fig. AS-2). Type maps show these are dominated by poor to medium stocking of old-growth ponderosa pine,³ i.e., trees over 53-cm. (21-in.) d.b.h. Minor amounts of Douglas-fir are normally associated. Typical measurements for dominant conifers are 75-cm. (30-in.) d.b.h. and 22 m. (75 ft.) in height. Hardwood tree

²Personal communication from Dr. R. H. Waring, Forestry Research Laboratory, Corvallis, Oregon.

³These are stocking levels according to standard timber inventory practices. Full (100-percent) stocking is defined by "normal stocking tables" and indicates complete occupation of the site by a tree species. Poor, medium, and good stocking are equivalent to 10 to 40, 40 to 70, and 70 to 100 percent, respectively, of the theoretical full stocking.

species present in such stands are California black and Oregon white oaks and Pacific madrone. The oaks typically attain diameters of 30 cm. (12 in.) at b.h. and heights of 10 to 12 m. (30 to 40 ft.); madrones may be somewhat larger (40-cm. or 16-in. d.b.h. and 15 m. or 50 ft. in height). Douglas-fir typically dominates whatever reproduction is present with smaller amounts of ponderosa pine. Both may be essentially absent, however, when a heavy understory of shrubs is present. The shrubby understory typically includes such sclerophyllous evergreen species as *Arctostaphylos patula* and *A. viscida*. In some stands the shrubs are gradually being killed off as Douglas-fir reproduction grows through and overtops them (fig. AS-2). Other common understory species are *Ceanothus integrifolius*, *Lotus crassifolius*, *Berberis nervosa*, *Achillea lanulosa*, *Solidago canadensis*, *Apocynum pumilum*, *Hieracium albiflorum*, *Madia madioides*, *Lupinus albifrons*, *Collomia* spp., *Agoseris retrorsa*, *Rhus diversiloba*, *Lonicera hispidula*, and grasses. These communities appear to relate most closely to Waring's (1969) "Black Oak Type"; Waring (1969) provides environmental and additional compositional data for this type.

The "Pacific Ponderosa Pine-Douglas-Fir" stands occupy the bulk of the natural area (fig. AS-2). Ponderosa pine is again conspicuous in the overstory, but it is consistently associated with medium to high stocking levels of Douglas-fir poles, second growth, and/or old growth. Conifers typically attain larger sizes — 75- to 100-cm. (30- to 40-in.) d.b.h. and 37 to 45 m. (125 to 150 ft.) tall. Douglas-fir is an important species in the tree reproduction, although reproduction of white fir is often present and may even be numerically dominant. Hardwood tree species are less common than in the Pacific ponderosa pine type. Understory shrubs include *Corylus cornuta* var. *californica*, chinkapin, *Holodiscus discolor*, *Symphoricarpos mollis*, and *Arctostaphylos patula*. *Rhus diversiloba* and *Lonicera hispidula* are generally absent. Subshrub and herbaceous species generally include those previously mentioned, but less hardy species such as *Trientalis latifolia*,

Adenocaulon bicolor, and *Polystichum munitum* are also common. These communities are mostly assignable to Waring's (1969) "Mixed Conifer Type," which indicates a significantly cooler and moister habitat than the aforementioned "Black Oak Type."

The forest stands assigned to the "Pacific Douglas-Fir" cover type differ from those outlined in the previous paragraph only in the minor role of ponderosa pine. Douglas-fir dominates the overstory with medium levels of stocking, and most of the reproduction is white fir (fig. AS-2). Ground vegetation is generally reduced under these denser stands, but the composition is typical of the "Mixed Conifer Type" (Waring 1969). The single stand of "Ponderosa Pine-Sugar Pine-Douglas-Fir" type differs only in 10- to 40-percent stocking of very large, old-growth sugar pine.

Although hardwoods are scattered throughout the natural area, there is one small, nearly pure stand of Pacific madrone 12- to 25-cm. (5- to 11-in.) d.b.h. It is located on top of a spur ridge just inside the natural area boundary south of Reeder Reservoir. Douglas-fir is the major conifer associate. The understory includes the relatively uncommon parasite *Boschniakia strobilacea*.

Most of the common animals of the southwestern Oregon pine-fir forest are found in the natural area. Mammals believed to utilize the tract as residents or transients are listed in table AS-1. Spiny lizards (*Sceloporus* spp.), striped skinks (*Eumeces* sp.), gopher snakes (*Pituophis melanoleucus*), and garter snakes (*Thamnophis* spp.) constitute the most common reptiles present. A great variety of bird life is represented, including species of hawks (Accipitridae), grouse (Phasianidae), quail (Tetraonidae), doves (Columbidae), owls (Tytonidae), woodpeckers (Picidae), jays (Corvidae), nuthatches (*Sitta* spp.), wrens (Troglodytidae), sparrows (Fringillidae), and the red-shafted flicker (*Colaptes cafer*).

Specialized habitats consist primarily of rock outcrops and cliffs and stream and streamside areas. There is a small ecologically interesting stand of *Cercocarpus betuloides* and *Bromus* sp. located on very shallow soil near Reeder Reservoir.

HISTORY OF DISTURBANCE

There is abundant evidence of wildfire occurrence within the natural area prior to the initiation of fire control programs about 1910. No major fires are known to have occurred within the area during recent years.

Human disturbance of the natural area is relatively minor despite its proximity to the city of Ashland. Access to the lower part of the natural area (Reeder Reservoir) is controlled, since this is the municipal water source for Ashland. Consequently, most disturbance is found along the bounding roads and extends only a short distance into the natural area. This type of marginal disturbance is expected to continue and probably increase in the future. There are some old mine workings, including buildings, within the northeastern edge of the tract.

RESEARCH

No research is presently known to be in progress on the natural area. However, numerous studies have been carried out in immediately adjacent areas on the ecology and environmental relations of the forest stands and tree species (Waring 1969, Cleary and Waring 1969, Atzet and Waring 1970). The results of these studies are directly

applicable to the natural area; the work of Whittaker (1960) should be applied with considerable caution, however, as it generally does not apply to conditions in the eastern Siskiyou Mountains. The flora of Mount Ashland, including the natural area, has been surveyed by Dennis (1959).

The natural area provides a site for studying the ecology of "Pacific" ponderosa pine-Douglas-fir forests over much of the range of environmental conditions in which it occurs. Studies of successional development within the variety of stand conditions and environments and their faunistic relationships are one example.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Ashland, Oregon-California quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1962; and *geology* — *Geology of the Medford Quadrangle, Oregon-California*, scale 1:96,000 (Wells 1956). Either the District Ranger (Ashland Ranger District) or Forest Supervisor (Rogue River National Forest, Medford, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Figure AS-1.— Ashland Research Natural Area,
Jackson County, Oregon.

Figure AS-2.—Natural features of the Ashland Research Natural Area. Upper left: General view of mixed ponderosa pine-Douglas-fir stands in the northeastern corner of the natural area; the East Fork of Ashland Creek is located in the canyon on the right. Upper right: Shrub community of *Arctostaphylos* spp. being overtopped and gradually killed off by conifers. Lower left: White fir reproduction under a mixed stand of sugar and ponderosa pine; white fir is the climax species and reproduces aggressively on more mesic portions of the natural area. Lower right: Old-growth ponderosa pine and Douglas-fir; note the severe fire scars left by past ground fires.

BAIRD BASIN RESEARCH NATURAL AREA¹

Typical northeastern Washington forests of ponderosa pine and Douglas-fir growing on north and south slopes and ridgetops.

The Baird Basin Research Natural Area was established in October 1959. It exemplifies typical northeastern Washington ponderosa pine (*Pinus ponderosa*), Douglas-fir (*Pseudotsuga menziesii*), and grand fir (*Abies grandis*) forest stands as they vary with land form (ridgetop and slope) and aspect (north and south). The 65-ha. (160-acre) tract is located in Stevens County, Washington, and is owned by the Bureau of Sport Fisheries and Wildlife. The area is administered as a part of the Little Pend Oreille Game Range, by the Washington Department of Game (Route 1, Colville, Washington). The rectangular area straddles a rolling hill and is located in the northwest portion of section 10, T. 34 N., R. 41 E., Willamette meridian, at 48°30' N. latitude, 117°40' W. longitude (fig. BB-1).

ACCESS AND ACCOMMODATIONS

The natural area is located about 49 km. (19 miles) east of Colville and is approached via State Highway 6A. An unmaintained logging road reaches the tract. Access is good during the summer, but snow creates difficulties during the winter. Public accommodations are available in Colville; there are primitive forest camps in the general area.

¹Description prepared by Dr. P. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

ENVIRONMENT

The Baird Basin Research Natural Area varies in elevation from 950 to 1,070 m. (3,100 to 3,500 ft.). It is located in rolling topography on a plateau glaciated during the Wisconsin period. Parent rocks appear to be granitic.

A modified continental climate prevails. Most precipitation occurs as snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Climatic data from Colville, located in a valley 48 km. (19 miles) to the east are as follows (U.S. Weather Bureau 1965):

Mean annual temperature	8.0°C. (46.5°F.)
Mean January temperature	-4.7°C. (23.6°F.)
Mean July temperature	20.4°C. (68.8°F.)
Mean January minimum temperature	-8.4°C. (16.8°F.)
Mean July maximum temperature	30.3°C. (86.7°F.)
Average annual precipitation	427 mm. (16.8 in.)
June through August precipitation	91 mm. (3.6 in.)

Soils in the area have not been mapped. Cursory examination suggests southerly slopes have colluvial soils derived from granitic material, whereas soils on gentle ridgetops and north slopes are developed in aerally deposited volcanic ash over buried profiles.

BIOTA

Estimated areas by forest cover type are:

Name	Area
Ponderosa pine with western larch and Douglas-fir	26 ha. (63 acres)
Douglas-fir and western larch	25 ha. (62 acres)
Lodgepole pine	14 ha. (35 acres)

The stands of ponderosa pine mixed with Douglas-fir and western larch (*Larix occidentalis*) can be assigned to SAF forest cover type 214, Ponderosa Pine-Western Larch-Douglas-Fir (Society of American Foresters 1954), and

Küchler's (1964) Type 12, Douglas Fir Forest. The Douglas-fir with western larch can be assigned to SAF type 212, Larch-Douglas-Fir, and Küchler's Type 12, Douglas Fir Forest. Lodgepole pine (*Pinus contorta*) forest belongs to SAF type 218, Lodgepole Pine; Küchler does not recognize lodgepole pine as a potential forest type. The area falls within the *Pseudotsuga menziesii* Zone (Daubenmire 1952).

Steep, southwest slopes with shallow, stony soils are generally dominated by ponderosa pine, bluebunch wheatgrass (*Agropyron spicatum*), Idaho fescue (*Festuca idahoensis*) and *Phlox* spp., with some elk sedge (*Carex geyeri*), *Lupinus* spp., and *Achillea millefolium* (fig. BB-2). It relates to Daubenmire and Daubenmire's (1968) *Pinus ponderosa*/*Agropyron spicatum* Association.

Ridgetops and gentle south slopes and swales are often dominated by ponderosa pine with occasional Douglas-fir. Douglas-fir reproduction and poles clearly dominate the understory. Ground vegetation is characterized by low to moderate crown cover of *Physocarpus malvaceus* and dense, vigorous pinegrass (*Calamagrostis rubescens*). Other ground vegetation species are *Symphoricarpos albus*, *Achillea millefolium*, and, occasionally, *Spiraea lucida* and *Arctostaphylos uva-ursi*. These stands typically grow on soils of aerially deposited pumice over residual granitic materials. They probably correlate with the *Pseudotsuga menziesii*/*Physocarpus malvaceus* Association (Daubenmire and Daubenmire 1968).

The most important north slope community is dominated by Douglas-fir with abundant western larch and an understory of *Physocarpus malvaceus* and Douglas maple (*Acer glabrum*), *Vaccinium scoparium*, pinegrass, *Linnaea borealis*, *Spiraea lucida*, *Berberis repens*, and *Hieracium albiflorum* are also present. This may represent a mesic phase of Daubenmire and Daubenmire's (1968) *Pseudotsuga menziesii*/*Physocarpus malvaceus* Association. It characteristically occupies soils of aerially deposited volcanic ash over granite.

The small lodgepole pine stand averages

70 to 90 years old. Lodgepole pine dominates with ground vegetation characterized by pinegrass, *Vaccinium scoparium*, *Chimaphila umbellata*, *Linnaea borealis*, *Spiraea lucida*, and occasional *Rosa gymnocarpa*, *Pachistima myrsinites*, and various forbs.

Resident and transient mammals believed to utilize the natural area are listed in table BB-1. Mule deer (*Odocoileus hemionus*) use the area as spring, summer, and fall range.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine indicate that ground fires periodically burned the area prior to initiation of fire control programs; four to eight wildfires are recorded in these scars. Dead and down trees in the lodgepole pine stand have been charred, clearly indicating a fire of conflagration proportions in that plant community.

Domestic livestock apparently grazed the tract to some extent between 1890 and 1930. There was no evidence of serious vegetational changes due to livestock use, however.

RESEARCH

No research is known on the area. It provides interesting opportunities: (1) to correlate vegetational gradients with variations in land form, slope, and aspect since the tract completely straddles a broad ridge; (2) to study development of forest stands in the absence of natural wildfires; and (3) to determine changes in biomass productivity with topography under a single macroclimate.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the Baird Basin Research Natural Area which are sufficiently detailed to be useful. The Game Range Manager (Little Pend Oreille Game Range) can provide details on the most recent aerial photo coverage of the area.

BLUEJAY RESEARCH NATURAL AREA¹

**Ponderosa pine/bitterbrush and
lodgepole pine/bitterbrush com-
munities located near the center of
the Mount Mazama pumice deposits
of south-central Oregon.**

The Bluejay Research Natural Area was established March 1971 to exemplify ponderosa pine/bitterbrush/needlegrass (*Pinus ponderosa*/*Purshia tridentata*/*Stipa occidentalis*) and lodgepole pine/bitterbrush/needlegrass (*Pinus contorta*/*Purshia tridentata*/*Stipa occidentalis*) communities characteristic of the central portion of the pumicite deposits resulting from the eruption of Mount Mazama (Crater Lake). The 85-ha. (210-acre) tract is located in Klamath County, Oregon, and is administered by the Chiloquin Ranger District (Chiloquin, Oregon), Winema National Forest (Klamath Falls, Oregon). The slightly rectangular area is located in the E1/2 of section 33, T. 30 S., R. 10 E., Willamette meridian, at 42°55' N. latitude and 121°30' E. longitude (fig. BJ-1).

ACCESS AND ACCOMMODATIONS

The natural area is located approximately 58 km. (36 miles) northeast of Chiloquin and is reached via U.S. Highway 97 and a gravel road. Access is good during summer but becomes difficult during the winter due to snow. Public accommodations are available in Chiloquin and Chemult; a primitive campground at Bluejay Springs is adjacent to the tract.

¹Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

ENVIRONMENT

The Bluejay Research Natural Area varies in elevation from 1,380 to 1,430 m. (4,540 to 4,700 ft.). Topography is flat to undulating with occasional slopes of 20 percent. The tract is located on a large plateau area over which dacite type pumice (bulk density of 0.6 to 0.8) was aerially deposited following the eruption of Mount Mazama (Baldwin 1964). All rocks and soil existing prior to the eruption have been covered with 2 to 25 dm. (1 to 10 ft.) of this pumice.

A modified continental climate prevails. Most precipitation occurs as snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Climatic data from Chemult, Oregon, located 40 km. (25 miles) northwest are as follows (U.S. Weather Bureau 1965):

Mean annual temperature5.3°C. (41.5°F.)
Mean January temperature-3.9°C. (25.0°F.)
Mean July temperature15.3°C. (59.6°F.)
Mean January minimum temperature-11.0°C. (12.1°F.)
Mean July maximum temperature	..28.1°C. (82.7°F.)
Average annual precipitation676 mm. (26.6 in.)
June through August precipitation66 mm. (2.6 in.)
Average annual snowfall417 cm. (164.0 in.)

Soils on the area have been mapped at a reconnaissance level. The Lapine loamy coarse sand, moderately deep phase, and a representative of the Wickiup series are present (U.S. Bureau of Indian Affairs 1958). A soil description obtained on the site, probably belonging to the Lapine series, is described below (see also fig. BJ-2). Pumice particles vary in size from coarse sand (1-mm. diameter) to pea gravel (5- to 10-mm. diameter) (fig. BJ-2). This soil is characteristic of the ponderosa pine/bitterbrush/needlegrass community:

01		Locally absent, pumice gravels on the surface, pine needles and shrub leaves under tree and shrub canopies.
A1	0 to 44 cm.	Dark brown when moist (10 YR 3/2) loamy coarse sand; not plastic or sticky with very fine weak granular structure; pH 6.2; no stones.
AC	4 to 30 cm.	Dark brown (10 YR 4/3 moist, 10 YR 7/3 dry) fine gravelly loamy coarse sand; not plastic or sticky, very weak subangular blocky structure; pH 6.4; no stones.
C1	23 to 74 cm.	Light yellowish brown (10 YR 7/6 moist, 10 YR 8/3 dry) very gravelly coarse sand; not plastic or stocky, single grained; pH 6.4; no stones.
C2	74 to 109 cm.	Light yellowish brown (10 YR 7/4 moist) fine gravelly coarse sand; not plastic or sticky, single grained; pH 6.6; no stones.
C3	109 to 117 cm.	Fine gravelly coarse sand and fine loamy sand; a mixed horizon of slightly plastic and sticky to non-plastic or -sticky with variable structure from moderate subangular blocky to single grained; pH 6.4; no stones.
IIBb	117 cm.+	Buried soil; brown (7.5 YR 4/4 moist) loamy sand; slightly plastic and slightly sticky with moderate subangular blocky structure; pH 6.6; 20 to 40 percent stones.

A Wickiup type soil occurs in swale topography at the west edge of the tract and currently supports lodgepole pine/bitterbrush/needlegrass.

BIOTA

Estimated areas by plant community are:

Name	Area
Ponderosa pine/bitterbrush/needlegrass	65 ha. (160 acres)
Lodgepole pine/bitterbrush/needlegrass	20 ha. (50 acres)

The ponderosa pine/bitterbrush/needlegrass stands can be assigned to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and Küchler's (1964) Type 10, Ponderosa Pine

Shrub. Lodgepole pine/bitterbrush/needlegrass communities belong to SAF forest cover type 218, Lodgepole Pine; Küchler does not recognize lodgepole pine as a type. The natural area falls within the *Pinus ponderosa* Zone (Franklin and Dyrness 1969).

The communities of ponderosa pine/bitterbrush/needlegrass fit the habitat type descriptions of Dyrness and Youngberg (1966) and Volland (1963) who worked in this general area. The plant community is dominated by ponderosa pine (*Pinus ponderosa*), bitterbrush (*Purshia tridentata*), and needlegrass (*Stipa occidentalis*) associated with *Carex rossii*, *Erigonum nudum*, *Viola purpurea* var. *purpurea*, and bottlebrush squirreltail (*Sitanion hystrix*). Ponderosa pine crown cover varies from 10 to 30 percent. Site index for ponderosa pine is 70 according to Meyer (1961); ponderosa pine basal area averages 16 sq. m. per hectare (70 sq. ft. per acre). All pines are growing slowly, suggesting near maximum stocking for the site (fig. BJ-2).

The lodgepole pine/bitterbrush/needlegrass community occurs in a swale topographic position on the tract's west edge. Lodgepole pine (*Pinus contorta*) dominates with bitterbrush, needlegrass, and some *Arctostaphylos uva-ursi*. It represents only moderate productivity according to Youngberg and Dahms (1970).

Resident and transient mammals believed to frequent the natural area are listed in table BJ-1. Mule deer (*Odocoileus hemionus*) utilize the area for spring, summer, and fall range.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine indicate ground fires periodically burned the area prior to initiation to fire control programs in 1910. According to these fire scars, the last wildfire occurrence was about 1916. Age classes of bitterbrush and ponderosa pine saplings suggest that both were established after the last ground fire.

Domestic sheep occasionally grazed the area in early spring. Ranger District records suggest sheep use never exceeded moderate levels and usually was light so domestic

animals have apparently not seriously affected the vegetation.

RESEARCH

Vegetation, soil description, and environmental notes for the pine/bitterbrush/needle-grass community are available.² No other research on the tract is known. However, relevant research in the general vicinity has been conducted by Dyrness and Youngberg (1966), Volland (1963), and Youngberg and Dahms (1970).

The Bluejay Research Natural Area provides interesting research opportunities: (1) to evaluate soils and vegetation in relation to the Mount Mazama pumice deposits in conjunction with Goodlow Mountain Research

²Research by L. A. Volland; available from the Division of Range and Wildlife Management, U.S. Forest Service, P.O. Box 3623, Portland, Oregon 97208.

Natural Area on the southwestern edge of Mazama deposit and the Metolius Research Natural Area located near the northern edge of aerially deposited pumice; (2) to compare microsite relations and biomass productivity of ponderosa pine and lodgepole pine; and (3) as a reference stand for undisturbed vegetation in the center of aerially deposited Mount Mazama pumice.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are sufficiently detailed to be useful. Either the District Ranger (Chiloquin Ranger District) or Forest Supervisor (Winema National Forest, Klamath Falls, Oregon) can provide details of the most recent aerial photo coverage of the area.

BREWER SPRUCE RESEARCH NATURAL AREA¹

**A mixed conifer type with abundant
Brewer spruce and associated brush-
fields on a rugged ridgetop in the
Siskiyou Mountains.**

The Brewer Spruce Research Natural Area was established on January 29, 1965. It exemplifies a high-elevation, mixed conifer type containing large amounts of Brewer spruce (*Picea breweriana*) and associated brushfields as they occur on mountain ridgetops in southwestern Oregon's Siskiyou Mountains. The 85-ha. (210-acre) area is located in Josephine County, Oregon, and is administered by the Medford District (Medford, Oregon), Bureau of Land Management (BLM). Administratively, it lies within the Deer Creek planning unit of the Applegate Resource Management Area. The tract occupies the N1/2 NW1/4 SW1/4 and SW1/4 NW1/4 SW1/4 of section 5, and the NE1/4 SE1/4, SW1/4 SW1/4, S1/2 NW1/4 SE1/4, SE1/4 NE1/4 SW1/4, SE1/4 SW1/4, and S1/2 of lot 7 in section 6, T. 39 S., R. 6 W., Willamette meridian. It lies at 42°12' N. latitude and 123°28' W. longitude.

ACCESS AND ACCOMMODATIONS

The area is accessible from the west (U.S. Highway 199 to the Illinois River Valley) via BLM's Deer Creek Access Road (No. 38-7-13); it can also be approached from the east via Williams and BLM's Cedar Flat Road (No.

39-5-6). These roads join at the intersection with the BLM's Rabbit Lake Road (No. 39-6-9), which passes within 91 m. (300 ft.) of the northern boundary of the natural area (fig. BP-1). Although an abandoned trail crosses the southwestern portion of the area, it is now very difficult to follow and foot travel through the area is slow and tedious.

The closest commercial accommodations are located in Cave Junction, about 16 km. (10 miles) to the southwest. Numerous and varied accommodations are also available in Grants Pass, situated about 49 km. (30 miles) to the north.

ENVIRONMENT

The Brewer Spruce Research Natural Area occupies the summit of a small mountain peak (Little Grayback Peak, elevation 1,861 m. or 5,445 ft.) and the crest of a downward-trending ridge extending in a northeasterly direction (fig. BP-2). With the exception of two small saddles located near the east and west boundaries, the area is extremely rugged, with steep slopes and numerous rock outcrops. Most of the steeply sloping portion has a northerly aspect. Elevations range from about 1,250 to 1,645 m. (4,100 to 5,400 ft.). A small cirque-like basin contains a small, shallow pond named Rabbit Lake.

The entire area is underlain by metavolcanic rocks of the Applegate Group (Wells, Hotz, and Cater 1949). These rocks were laid down during the Triassic period. In the natural area they are apparently largely metamorphosed andesites and basalts.

The climate is warm-temperate with hot, dry summers and cool, moist winters. Much of the winter precipitation occurs as snow. Cumulative winter snowpacks may exceed 3 m. (10 ft.) and they are not completely melted until midsummer. The following climatic data are from the Williams weather station, which is about 14 km. (9 miles) east

¹ Description prepared by Dr. C. T. Dyrness, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

of and 915 m. (3,000 ft.) below the natural area (Whittaker 1960, U.S. Weather Bureau 1965):

Mean annual temperature11.1°C. (52.0°F.)
Mean January temperature3.7°C. (38.7°F.)
Mean July temperature19.4°C. (66.9°F.)
Extreme minimum temperature ...-16.0°C. (3.0°F.)
Extreme maximum temperature ...42.0°C. (108.0°F.)
Average annual precipitation ..957 mm. (37.69 in.)
June through August
precipitation32 mm. (1.24 in.)

Temperatures are undoubtedly considerably lower and precipitation somewhat higher on the natural area.

Very little is known about the soils of the area. Steepness of the terrain and high frequency of rock outcrops indicate most soils are undoubtedly shallow and immature with high stone contents. A profile examination near the southwestern corner of the area disclosed a regosolic soil containing about 60 percent stones, with a dark brown, silt loam surface horizon.

BIOTA

It is difficult to place the Brewer Spruce Research Natural Area within a single vegetation zone. In fact, it contains elements of three vegetation zones defined by Franklin and Dyrness (1969) for southwestern Oregon: the Mixed Conifer, *Abies concolor*, and *Abies magnifica shastensis* Zones. The area includes Kuchler's (1964) Types 5, Mixed Conifer Forest (*Abies-Pinus-Pseudotsuga*), and 34, Montane Chaparral (*Arctostaphylos-Castanopsis-Ceanothus*). The forest stands appear to be a mixture of SAF cover types 207 (Red Fir) and 211 (White Fir) with possibly some areas classifiable as cover type 243 (Ponderosa Pine-Sugar Pine-Fir) (Society of American Foresters 1954).

At least 10 different coniferous tree species grow in the natural area. The most common of these are: Douglas-fir (*Pseudotsuga menziesii*), white fir (*Abies concolor*), Brewer spruce (fig. BP-2), Shasta red fir (*Abies magnifica* var. *shastensis*), western white pine (*Pinus monticola*), Pacific yew (*Taxus brevifolia*), and Port-Orford-cedar (*Chamaecyparis*

lawsoniana). Coniferous tree species more limited in distribution include sugar pine (*Pinus lambertiana*), knobcone pine (*Pinus attenuata*), and incense-cedar (*Libocedrus decurrens*). Another outstanding feature of the area is the rather extensive brushfields. The Bureau of Land Management estimates that only about 60 percent of the area is forested, 25 percent is brushfield, and the remaining 15 percent is made up of bare rock outcrops and talus.

Most of the older (200- to 300-year-old or more) forest stands in the area are very open with a total overstory coverage of only 25 to 30 percent (fig. BP-2). Brewer spruce and Douglas-fir are generally codominant in the overstory; minor amounts of western white pine may also be present. Tree regeneration in some locations is dominated by Port-Orford-cedar saplings which have a stunted appearance, probably due to heavy snow loads. In most areas, however, both Shasta red fir and Brewer spruce appear to be reproducing successfully, each with about 5-percent reproduction coverage in a typical stand. Western white pine and Douglas-fir are also scattered individually through the understory. The most abundant understory shrub is *Vaccinium membranaceum*. Other more scattered shrubs include *Amelanchier pallida*, *Arctostaphylos patula* and *A. nevadensis*, *Ceanothus prostratus*, *Castanopsis chrysophylla*, *Berberis nervosa*, *Rosa gymnocarpa*, and Pacific yew. Typical herbaceous species in these open timberstands include *Achlys triphylla*, *Chimaphila umbellata*, *Pedicularis racemosa*, *Hieracium albiflorum*, *Xerophyllum tenax*, *Senecio triangularis*, and *Pyrola secunda*.

The Brewer spruce-Shasta fir stand just southeast of and above Rabbit Lake probably contains the best specimens of Brewer spruce in the area. Scattered large individuals range up to about 1-m. (3-ft.) d.b.h. The understory is dominated by thickets of sapling-sized Port-Orford-cedar, although both Brewer spruce and Shasta fir are apparently reproducing successfully.

An area of young, dense white fir occurs near the western boundary. Although the stand is dominantly 90- to 100-year-old white

fir, significant amounts of Shasta red fir and western white pine are also present in the overstory. Tree regeneration consists of scattered white fir and western white pine. The shrub layer has about 15-percent *Berberis nervosa* cover, with lesser amounts of Pacific yew, *Castanopsis chrysophylla*, *Amelanchier pallida*, *Holodiscus discolor*, and *Rosa gymnocarpa*. The herb layer has low coverage; some of the principal species are several grasses, *Chimaphila umbellata*, *Arenaria macrophylla*, *Trientalis latifolia*, *Osmorhiza chilensis*, *Synthyris reniformis*, *Arnica latifolia*, *Disporum hookeri*, *Trillium ovatum*, *Dicentra formosa*, *Anemone deltoidea*, and *Polystichum munitum*.

Extensive tracts of extremely dense, tall (3-m. or 10-ft.) shrubs with only very scattered tree cover occur on steep north and northwest-facing slopes adjacent to rock outcrops. The hardy, isolated trees dotting these shrub communities are usually white fir, Shasta red fir, Brewer spruce, and, occasionally, western white pine. The dominant shrub species is generally Pacific yew, which sometimes forms almost impenetrable thickets. Other shrubs which may be important components of the stand include *Acer glabrum* var. *torreyi*, *Holodiscus discolor*, *Corylus cornuta* var. *californica*, *Quercus vaccinifolia*, *Amelanchier pallida*, and *Rubus parviflorus*. On similar sites, which perhaps have been more recently disturbed by fire, are scattered young trees with *Vaccinium membranaceum* and *Xerophyllum tenax* as the principal understory.

Low (about 1-m. or 3-ft.) brushfields are rather extensive in southeastern and southwestern portions of the natural area in section 6 (fig. BP-2). The most important contributions to the dense shrub cover are *Arctostaphylos patula* and *Quercus vaccinifolia*. Other shrub species of more scattered occurrence include *Ceanothus velutinus*, *Holodiscus discolor*, *Corylus cornuta* var. *californica*, *Quercus garryana* var. *breweri*, and *Quercus chrysolepis*.

The 1/4-ha. (0.5-acre) Rabbit Lake constitutes an interesting aquatic habitat in the natural area (fig. BP-2). Snowmelt apparently supplies the water for this shallow pond. Out-

flow occurs only during the spring and by late summer the shoreline has receded considerably. Although the pond is too shallow to support fish, it undoubtedly serves as a habitat for amphibians. The area near the shoreline supported the following plant species which were not observed elsewhere: *Veratrum californicum*, *Ribes lacustre*, *Salix* sp., *Clin-tonia unifoliata*, *Tiarella unifoliata*, and *Linnæa borealis* ssp. *longiflora*.

Resident and transient mammals believed to utilize the natural area are listed in table BP-1.

HISTORY OF DISTURBANCE

There is no evidence of recent fires within the Brewer Spruce Research Natural Area. However, the area has probably been repeatedly burned in the more distant past.

Human disturbances chiefly involve several clearcut areas logged in 1964. These extend into the natural area in two locations along the northern boundary. The total clearcut area within the boundaries of the natural area is estimated to be less than 4 ha. (10 acres).

Some of the developments planned for the area may result in some additional disturbance. The Bureau of Land Management plans to reconstruct approximately 0.8 km. (0.5 mile) of foot trail within the natural area. This trail will be a segment of a 15-km. (9-mile) scenic trail. A spur trail, lying outside the natural area, is proposed from the end of the Rabbit Lake Road in section 6 to an intersection with the main scenic trail in the SW1/4 of section 6. Plans also call for installation of plant identification signs for 30 to 40 of the most common species within the natural area.

RESEARCH

No research is presently being conducted within the natural area. Although both Whitaker (1960) and Waring (1969) studied forest ecology in nearby areas, neither is known to have included the Brewer Spruce Research Natural Area in his investigations.

MAPS AND AERIAL PHOTOGRAPHS

Maps applicable to the natural area are: *Topography* — 15' Oregon Caves, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1954; and *geology* — *Preliminary Geologic Map of Southwestern Oregon*, scale 1:500,000 (Wells 1955) and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961).

The District Manager (Medford District), Bureau of Land Management, can provide details on the most recent aerial photo coverage and any forest type maps which may be available for the area.

BULL RUN RESEARCH NATURAL AREA¹

Mixed stands of noble fir, Pacific silver fir, western hemlock and Douglas-fir on the slopes of a cirque in the Oregon Cascade Range.

The Bull Run Research Natural Area was established on April 8, 1966. It exemplifies the mixed true fir (*Abies* spp.), hemlock (*Tsuga* spp.), and Douglas-fir (*Pseudotsuga menziesii*) forests found at middle elevations in central portions of the Cascade Range. The 146-ha. (361-acre) tract is located in Clackamas County, Oregon, and is administered by the Columbia Gorge Ranger District (Springdale, Oregon), Mount Hood National Forest. The natural area lies immediately west of the Cascade Range divide at the head of the Bull Run drainage and on the eastern slope of Sentinel Peak and northern slope of Hiyu Mountain (fig. BR-1). It occupies portions of sections 27 and 34, T. 1 S., R. 8 E., Willamette meridian. Major bounding features are an old firebreak along the northeast and east, the 1,000-m. (3,280-ft.) contour on the west, and a rockslide on the northwest (fig. BR-1). The natural area lies at 45°26' N. latitude and 121°49' W. longitude.

ACCESS AND ACCOMMODATIONS

Since this natural area lies within the Bull Run watershed, the municipal water supply for Portland, access is strictly controlled. It is necessary to obtain an entry permit and, possibly, a key from the Ranger District before entering the watershed, regardless of the

¹Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

approach route. This is in addition to obtaining permission to conduct research on the natural area itself.

Access to this natural area is either by foot or by boat. The simplest approach is probably by about 0.4 km. (0.25 mile) of unmaintained trail from the top of Hiyu Mountain. This trail drops about 180 m. (600 ft.) down the old firebreak on the north slope of the mountain before reaching the natural area. The summit of Hiyu Mountain is best reached via Forest Roads N12 (Lolo Pass road) and S10 from Zigzag on U.S. Highway 26, a distance of about 25 km. (16 miles). The other approach is by boat from the lower (western) end of Bull Run Lake. This can be reached either from the Sandy area via Forest Road S10 or from Zigzag via Forest Roads N12 and S10. If repeated visits are planned, heavy research equipment is involved, or the lower or northern portions of the natural area are of most interest, the lake approach is recommended. Boat rentals are not available.

The nearest commercial accommodations are at Rhododendron and along adjacent portions of U.S. Highway 26. Developed forest campgrounds are also found in this area and along the Lolo Pass road (Forest Road N12).

ENVIRONMENT

The Bull Run Research Natural Area is located on mountain slopes in a cirque adjacent to the crest of the Cascade Range (fig. BR-3). Topography is generally steep, with slopes commonly 30 to 60 percent in the southern half and in excess of 60 percent in the northern half of the area. Relatively gentle slopes and benches occupy limited area. Springs are common in middle and lower portions of the natural area, and streams have cut sharp, steep-walled canyons in several locations. Limited areas of rock slides (talus) are present (fig. BR-3). Elevations range from 1,000 to 1,370 m. (3,280 to 4,500 ft.).

Vulcanism and glaciation have been the primary geologic processes within the natural area. Bedrock is composed primarily of basalts and andesites belonging to the Cascade Andesite formation² and Pliocene-Pleistocene in age (Peck 1961). Pleistocene glaciation affected almost the entire Bull Run drainage, and at least two glacial advances are evident. Bull Run Lake itself lies behind a classical example of a terminal moraine. Compacted glacial till is present in several locations.

The climate of the natural area is cool and wet. Total precipitation, measured nearby at the outlet of Bull Run Lake, averaged 3,125 mm. (123 in.) between 1961 and 1967³. Summers are relatively dry (about 200 mm. or 8 in.) in July through September. The bulk of the precipitation occurs during the winter months, and much of this accumulates in snowpacks which probably attain maximum depths of 2 to 3 m. (6 to 9 ft.) on the average. Temperature data are not available for the area, and the nearest climatic station (U.S. Weather Bureau 1965) is at low elevation in the foothills about 29 km. (18 miles) to the west at the Portland Water Bureau's Headquarters.

Soils in the natural area have been mapped (fig. BR-2) and described as part of a general soil survey of the Bull Run drainage.⁴ They are Podzols developed in glacial till and are classified into two tentative soil series — Jackpot and Last Chance. The Jackpot soil is the more productive and usually contains an indurated till layer. A generalized profile description is as follows:

01 and 02	4 to 0 cm.	Organic matter.
A2	0 to 4 cm.	Black (moist color) silt loam with very fine granular structure, pH 4.6.

²Information from "Interim Soil Survey Report of the Bull Run Watershed Portion of the Bull Run-Sandy Soil Survey Area," by F. R. Stephens. 1962. Typewritten inservice report, 65 p., illus. USDA Forest Service, Region 6, Portland, Oregon.

³Unpublished data provided by J. Rothacher, U.S. Forest Service, Forestry Sciences Laboratory, Corvallis, Oregon.

⁴See footnote 2.

A31	4 to 15 cm.	Very dark brown gravelly silt loam with weak, fine, subangular blocky structure, pH 4.6.
A32	15 to 32 cm.	Very dark brown gravelly silt loam with weak, fine and medium subangular blocky structure, pH 4.8.
B2	32 to 53 cm.	Dark brown, stony, gravelly light clay loam with weak, fine subangular blocky structure, 50 percent stone volume, pH 5.0.

A typical Last Chance profile is generally more strongly podzolized:

01 and 02	5 to 0 cm.	Organic matter.
A2	0 to 4 cm.	Gray and dark gray (moist color) sandy loam with weak, coarse platy to massive structure, pH 4.2.
B2ir	4 to 15 cm.	Dark brown and dark reddish brown, stony, gravelly loam, massive to very weak, fine subangular blocky structure, 30 percent stones and 45 percent gravel, pH 4.4.
B3	15 to 25 cm.	Brown to dark brown, stony, gravelly loam, massive, 30 percent stones and 45 percent gravel, pH 4.6.
C	25 to 70 cm.	Brown, stony gravelly loam, pH 4.8.
D	70 to 160 cm.	Brown, stony gravelly loam, pH 5.0.

The D horizon may or may not be present, and A2 horizons vary from 1 to 8 cm. in thickness. Bedrock may lie 1 to 65 m. or more below the morainal deposits in the case of either soil series.

BIOTA

All 146 ha. (361 acres) of the Bull Run Research Natural Area are classified as SAF cover type 226, Pacific Silver Fir-Hemlock (Society of American Foresters 1954). The area falls within Küchler's (1964) Types 3 or 4 (Silver Fir-Douglas Fir or Fir-Hemlock Forest) and the *Abies amabilis* Zone of Franklin and Dyrness (1969).

Forest stands in the natural area are a mixture of noble fir (*Abies procera*), Pacific silver fir (*Abies amabilis*), western hemlock (*Tsuga heterophylla*), and Douglas-fir. The first three

species are common throughout the entire natural area, while Douglas-fir tends to be only a minor component or absent in the stands above 1,100 m. (3,600 ft.). Mountain hemlock (*Tsuga mertensiana*) occurs at higher elevations. The forests in the area are all old growth with an estimated age in excess of 250 years. The largest trees in the stand are generally noble fir (fig. BR-3) and Douglas-fir, followed by western hemlock and Pacific silver fir, in that order. Mensurational data are not available, but dominant trees on better sites are often 90- to 130-cm. (35- to 50-in.) d.b.h. and over 45 m. (150 ft.) tall.

Size and age class distributions indicate Pacific silver fir is the major climax species throughout the natural area. Pacific silver fir seedlings, saplings, and poles are by far the most numerous in the stands. Western hemlock appears to be either intermediate successional or a minor climax species on some sites. Douglas-fir and noble fir are clearly pioneer species and are gradually being eliminated by mortality.

Two major plant communities are common within the natural area⁵ which probably belong to the *Abies amabilis*/*Streptopus curvipes* and *Abies amabilis*/*Vaccinium alaskaense* Associations (Franklin 1966). The *Abies amabilis*/*Streptopus curvipes* Association typifies the more productive sites and Jackpot soil series. The dense, herbaceous understory includes *Vancouveria hexandra*, *Streptopus curvipes*, *Achlys triphylla*, *Asarum caudatum*, and *Oplopanax horridum*. The *Abies amabilis*/*Vaccinium alaskaense* Association is found on poorer sites and Last Chance soils. *Vaccinium alaskaense*, *V. membranaceum*, *Menziesia ferruginea*, *Cornus canadensis*, *Xerophyllum tenax*, and *Gaultheria ovatifolia* are common understory plants. The presence of *Rhododendron macrophyllum* contrasts with its absence in similar *Abies amabilis*/*Vaccinium alaskaense* communities north of the Columbia River in the Washington Cascade Range.

Mammals believed to occur as either residents or transients within the natural area are listed in table BR-1. The ruffed grouse

(*Bonasa umbellus*) is an important resident gamebird.

Specialized habitats within the natural area include spring and seep areas, the several permanent streams, and open talus or rock slides (fig. BR-3).

HISTORY OF DISTURBANCE

The natural area is essentially free of any human disturbance. Minor disturbances due to transient fishermen, hunters, hikers, etc. are, and will continue to be, absent due to the strict control over access to the Bull Run drainage. The bounding firebreak has regenerated with young trees, and any minor edge effects it has caused should decline rapidly in the future.

The natural area also appears to have been free of significant natural disturbances, such as wildfire in recent decades.

RESEARCH

There is no history of research in Bull Run Research Natural Area except in connection with the general soil survey.

The natural area is particularly valuable as a site for studies of the mixed stands typical of the transition zone between temperate and subalpine forests. Two contrasting soil and community types can be compared within the tract. Specialized areas available for study include the aquatic and semiaquatic habitats and rock slides; these may be of special interest for zoological studies.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 7.5' Bull Run Lake, Oregon quadrangle, scale 1:24,000, issued by the U.S. Geological Survey in 1962; and *geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (Columbia Gorge Ranger District) or Forest Supervisor (Mount Hood National Forest, Portland, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

BUTTER CREEK RESEARCH NATURAL AREA¹

A subalpine mosaic of forest, shrub, and meadow communities in a rugged 2,000-acre drainage in the Washington Cascade Range near Mount Rainier.

Butter Creek Research Natural Area exemplifies an entire mosaic of subalpine communities including closed forest, parkland, shrubfields, and meadows. The 810-ha. (2,000-acre) tract is located in Lewis County, Washington, and administered by Mount Rainier National Park (Longmire, Washington). The natural area includes all of Butter Creek drainage within the park; consequently, boundaries follow natural topographic features (ridge and mountain summits) except along the southern edge (fig. BU-1). It lies at 46° 45' N. latitude and 121° 44' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area occupies a rugged drainage lacking trails and roads; consequently access is by cross-country travel which is frequently difficult and requires care. The upper end of the natural area is reached via the Pinnacle Peak trail which terminates at the edge of the tract in the saddle between Pinnacle and Plummer Peaks. Most of the meadow areas can be reached from this point by easy to moderately difficult cross-country travel. A Forest Service logging road up Butter

Creek terminates in a clearcut about 0.8 km. (0.5 mile) south of the park boundary; the lower part of the natural area is reached in this way with Butter Creek itself providing the easiest cross-country route from the roadhead into the tract.

Commercial accommodations are located nearby at Longmire and Paradise Valley in the National Park and at Ashford and Packwood. There are numerous improved campgrounds in adjacent portions of Mount Rainier National Park and the Gifford Pinchot National Forest.

ENVIRONMENT

The natural area occupies the entire upper drainage of Butter Creek, including two major branches which are effectively divided for most of their length by a large downward trending ridge (fig. BU-1). This is one of the major drainage basins on the south slopes of the Tatoosh Range, an intruded mountain massif of east-west orientation. Various mountain peaks and ridges of this range, such as Wahpenayo, Lane, Pinnacle, Plummer, Unicorn, and Boundary Peaks, form a semicircular rim for the northerly boundaries of the tract (fig. BU-3). The natural area spans a wide range in elevations varying from about 1,040 m. (3,400 ft.) along Butter Creek to 2,116 m. (6,939 ft.) at the summit of Unicorn Peak. It also incorporates a variety of mountain landforms from precipitous rock outcrops to nearly level valley bottom. Gentle topography is confined to the valley bottoms along the lower reaches of Butter Creek and to occasional benches at higher elevations. Most of the natural area consists of moderate to steep (30- to 90-percent) mountain slopes, some of which are continuous over nearly the entire elevational span (fig. BU-3). Precipitous topography is most common along the bounding ridges and at intermediate elevations along the west branch of Butter Creek.

¹ Description prepared by Dr. C. T. Dyrness and Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

The natural area incorporates several miles of perennial stream. In addition, there are at least four ponds or lakes within the natural area, all located in the subalpine parkland. Three of these are located at about 1,555 m. (5,100 ft.) in the northwestern corner of the natural area on the slopes below Lane Peak. Cliff Lake, the largest, covers about 2.2 ha. (5.5 acres) and has a maximum depth of 9 m. (30 ft.) (Wolcott 1961). An unnamed lake (about 0.4 ha. or 1 acre in size and shallow) and a smaller pond are located about 300 m. (1,000 ft.) southwest of Cliff Lake. No fish inhabit either of the lakes (Wolcott 1961). The fourth pond is located just inside the northeastern corner of the natural area in the saddle between Pinnacle and Unicorn Peaks.

The geology of the Butter Creek Research Natural Area is probably better known than any other aspect of its natural history (Crandell 1969a, 1969b; Fiske, Hopson, and Waters 1963). The bulk of the natural area is located on Miocene-Pliocene intrusive igneous rocks (Fiske, Hopson, and Waters 1963) (fig. BU-2). These are the granodiorites and quartz monzonites of the Tatoosh pluton; included are subordinate amounts of quartz diorite, contact breccia, and fine-grained border rocks. Oligocene-Miocene volcanic rocks belonging to the Stevens Ridge formation dominate the western third of the natural area and occur along the bounding ridges elsewhere. These consist of rhyodacite ash flows with subordinate amounts of volcanic breccia and sandstones and siltstones of epiclastic and pyroclastic origin. The oldest volcanic rock formation, the Ohanapecosh, occupies a small area in the lower reaches of Butter Creek. The volcanic breccias and associated epiclastic and pyroclastic sandstones and siltstones of this formation are of Eocene age. Finally, small areas of dioritic rocks and of basaltic and andesitic rocks belonging to the Fife Peak formation occur in alternating layers near the summit of Unicorn Peak.

Existing landforms and surficial geology are primarily the result of stream erosion and glaciation. Glaciers have occupied the drainage periodically (Crandell 1969b) and are responsible for the alplike appearance of the

upper ridge and the U-shaped valley of the west branch of Butter Creek. The surficial geology of most of the tract appears to be relatively simple, undifferentiated bedrock types (Crandell 1969a). However, blockfield deposits are identified on the slopes below Pinnacle Peak and the ridgetop along the east boundary. In addition, taluses occur mainly on the slopes below the northwest boundary ridgetop from Wahpenayo to Lane Peaks (fig. BU-2).² Recent aeolian deposits of volcanic ejecta also blanket much of the natural area. These deposits are largely made up of pumice and volcanic ash of varying age. Ash layers W and Y from Mount St. Helens, which are about 450 and 3,250 to 4,000 years old, respectively, are known to occur on the tract (Crandell 1969b).

A wet, cool maritime climate prevails. Annual precipitation is heavy, with maxima in December and January and minima in July and August. Summers are generally cool with frequent cloudy days, but only about 10 percent of the precipitation occurs from June through August. A winter snowpack develops over the entire natural area, but its depth and total annual snowfall increase rapidly with elevation. The range of climatic conditions encountered on the natural area are approximated by the following data from the Longmire and Paradise Valley weather stations, 5 and 3 km. (3 and 2 miles) west and north of the natural area, respectively (U.S. Weather Bureau 1965):

	<i>Longmire</i>	<i>Paradise Valley</i>
Elevation	842 m. (2,762 ft.)	1,821 m. (5,950 ft.)
Mean annual temperature .	7.3°C. (45.1°F.)	3.4°C. (38.2°F.)

² Blockfield deposits consist of angular rock fragments pried from underlying formations by freeze-thaw cycles of moisture in cracks. Taluses are loose accumulations of coarse and typically fresh and angular rock fragments with steeply sloping surfaces. Taluses can be differentiated from blockfield deposits by their location beneath cliffs and the wide range in rock fragment size from pieces a few centimeters across to blocks 10 m. or more in maximum diameter (Crandell 1969a).

	Longmire	Paradise Valley
Mean January temperature	-0.9°C. (30.3°F.)	-3.4°F. (25.8°F.)
Mean July temperature	16.2°C. (61.2°F.)	11.6°C. (52.8°F.)
Mean January minimum temperature	-4.1°C. (24.5°F.)	-7.0°C. (19.4°F.)
Mean July maximum temperature	23.8°C. (74.9°F.)	17.4°C. (63.3°F.)
Average annual precipitation	2,094 mm. (82.43 in.)	2,635 mm. (103.73 in.)
June through August precipitation	171 mm. (6.73 in.)	226 mm. (8.91 in.)
Average annual snowfall . .	474 cm. (186.5 in.)	1,362 cm. (537.4 in.)

Soils in the forested lower end of the natural area are largely Podzols and Regosols with limited areas of Alluvial soil in terrace positions along Butter Creek. The podzolic soils are formed primarily in layers of pumice and volcanic ash which have been aerally deposited over the surface of the bedrock. A typical soil on relatively gentle terrain just north of the confluence of the two major branches of Butter Creek exhibited the following horizons:

01 and 02	7 to 0 cm.	Forest floor material of varying stages of decomposition.
A2	0 to 2 cm.	Light gray sand-size pumice.
B2	2 to 20 cm.	Dark brown loam with high pumice content and some pockets of fresh pumice.
IIAb	20 to 25 cm.	Very dark grayish brown loamy sand.
IICb	25 to 32 cm.	White unweathered pumice sand with brownish yellow pockets caused by iron staining.
IIIB2b	32 to 45 cm.	Brown pumiceous silt loam over bedrock (granodiorite).

Some gravels and cobbles are typically intermixed with the volcanic ash and pumice, especially in the buried horizons. Regosolic soils on steeper slopes are intimate mixtures of pumiceous materials and rock fragments showing little evidence of profile development.

Much of the upper, nonforested portion of the natural area consists of steep slopes

characterized by talus and blockfield deposits. However, on more gentle terrain at high elevations are tracts of Alpine Turf and Alpine Meadow soils. These soils are characterized by black, generally thick A horizons underlain by a stony substratum.

BIOTA

There are at least four major categories of subalpine plant communities found within the Butter Creek Research Natural Area: (1) forests of Pacific silver fir (*Abies amabilis*), western hemlock (*Tsuga heterophylla*), and noble fir (*Abies procera*) typical of middle elevations in the Cascade Range; (2) subalpine forests typified by mountain hemlock (*Tsuga mertensiana*) and Pacific silver fir which ranged from a continuous closed canopy to isolated, patchy tree groups found near timberline; (3) shrub communities, generally dominated by Sitka alder (*Alnus sinuata*), or Alaska-cedar (*Chamaecyparis nootkatensis*), and vine maple (*Acer circinatum*); and (4) subalpine meadows of widely variable composition and structure. Each of these categories covers a significant area although no quantitative breakdown is available. SAF cover types represented include 226, Pacific Silver Fir-Western Hemlock, and 205, Mountain Hemlock-Subalpine Fir (Society of American Foresters 1954). Küchler's (1964) Types 3, Silver Fir-Douglas Fir Forest; 4, Fir-Hemlock Forest; and 52, Alpine Meadows and Barren, are present. Lower elevations fall within the *Abies amabilis* Zone (Franklin and Dyrness 1969) and higher elevations cover both the closed forest and parkland (forest-meadow mosaic) subzones of the *Tsuga mertensiana* Zone (Franklin and Bishop 1969). True alpine vegetation is probably not present; precipitous slopes preclude vegetational development at the highest elevations (over about 6,300 ft. or 1,900 m.) where it might be expected.

Reconnaissance of the natural area was unusually limited in view of its large size and complexity. On-the-ground examination has been restricted to subalpine meadow areas near the northern boundary and several

forested sites adjacent to Butter Creek at the southern boundary. Sites occupied by shrubs and young trees which cover much of the central portion of the tract received only limited attention.

Forest communities in the southern portion of the natural area (*Abies amabilis* Zone) include seral stages of the *Abies amabilis/Vaccinium alaskense*, *Abies amabilis/Streptopus curvipes*, and *Abies amabilis/Oplodanax horridum* Associations described by Franklin (1966). Near the southern boundary stream, terraces adjacent to Butter Creek are occupied by an open, seral phase of the *Abies/Vaccinium* Association. Tree overstory is very scattered and made up of about equal amounts of noble fir and Pacific silver fir. Although both silver fir and western hemlock are also present, tree regeneration is generally dominantly noble fir. The dense shrub layer, dominated by *Vaccinium alaskense*, also includes vine maple, *Rubus spectabilis*, and *Sambucus racemosa*. The most important herbs are *Clintonia uniflora* and *Pteridium aquilinum*, with smaller amounts of *Anaphalis margaritacea*, *Achlys triphylla*, *Tiarella unifoliata*, *Veratrum viride*, and *Smilacina stellata*.

An open, seral phase of the *Abies amabilis/Streptopus curvipes* Association occupies rather extensive areas on moderate to steep slopes above Butter Creek. The overstory is made up of scattered, often very large noble fir (fig. BU-3) along with smaller Pacific silver fir. A thicketlike understory of vine maple makes travel through the area very difficult. Other species of some importance in these stands include *Pachistima myrsinites*, *Achlys triphylla*, *Clintonia uniflora*, *Streptopus curvipes*, *Pteridium aquilinum*, *Galium triflorum*, *Polystichum munitum*, and *Rubus lasiococcus*. In wetter areas this community gives way to the *Abies amabilis/Oplodanax horridum*.

The *Abies/Streptopus* Association is also found with a dense tree overstory but only at scattered locations at low elevations. Dominant trees are old-growth Douglas-fir (*Pseudotsuga menziesii*) and western hemlock, with Pacific silver fir the most abundant species in the understory. The shrub layer is scattered, comprised of such species as *Acer circina-*

tum, *Vaccinium alaskense*, and *Rubus spectabilis*. The herb layer is well developed and typically includes *Achlys triphylla*, *Gymnocarpium dryopteris*, *Tiarella unifoliata*, *Streptopus curvipes*, *Rubus pedatus*, *R. lasiococcus*, *Viola sempervirens*, *Chimaphila menziesii*, *Pyrola asarifolia*, and *Trillium ovatum*.

The forests occupying the *Tsuga mertensiana* Zone were examined to only a minor extent. Tree species present include mountain hemlock, Pacific silver fir, subalpine fir (*Abies lasiocarpa*), and whitebark pine (*Pinus albicaulis*). As mentioned, conditions vary widely from closed stands of both young and old age to small tree groups surrounded by meadows (fig. BU-3). In general, Pacific silver fir is less common in the parkland subzone above the line of continuous forest, and whitebark pine is uncommon in the lower elevation, closed forest. Community types probably include the *Abies amabilis-Tsuga mertensiana/Vaccinium membranaceum* and *Abies amabilis/Menziesia ferruginea* Associations described by Franklin (1966) as well as others.

Shrub communities are of several types. Stands dominated by 3- to 5-m. (9- to 15-ft.) tall Sitka alder, vine maple, or Alaska-cedar are believed to be topographic or topoedaphic climax types. They probably owe origin and maintenance to special environmental conditions, such as an extremely stony substrate and recurring snow avalanches. The effects of heavy snowloads are evident in the strong bowing of Sitka alder stems, and the resilience of the stems allows them to bend under avalanching rather than break. The avalanche communities are especially common on the slopes above the west branch of Butter Creek (fig. BU-3). In general, vine maple apparently dominates brushfields on drier sites and Sitka alder and Alaska-cedar on moister sites. An earlier description of the area (Anonymous 1942) mentions brushfields with *Rhododendron albiflorum* and *Sorbus occidentalis* as major components. These have not been seen and may be misidentifications of the maple, alder, or Alaska-cedar communities.

Subalpine meadow vegetation begins at about 1,585-m. (5,200-ft.) elevation, although

most occurs between 1,675 and 1,830 m. (5,500 to 6,000 ft.). The extensive steeply sloping portion of this headwaters area is south-facing with very shallow soils (fig. BU-3). As a result, the habitat is relatively warm and dry during the growing season and supports two closely related subalpine meadow types characteristic of such habitats. These have tentatively been named the *Festuca viridula*/*Lupinus latifolius* and *Festuca viridula*/*Aster ledophyllus* types.³ The *Festuca*/*Aster* community occurs on the driest portion of the slopes and includes as dominants the following species: *Festuca viridula*, *Aster ledophyllus*, *Carex spectabilis*, *Castilleja miniata*, *Erigeron salsuginosus*, *Agoseris alpestris*, *Lupinus latifolius*, *Polygonum bistortoides*, and *Phlox diffusa*. The most important species in the *Festuca*/*Lupinus* community are: *Festuca viridula*, *Lupinus latifolius*, *Carex spectabilis*, *Polygonum bistortoides*, *Castilleja oreopola*, *Pedicularis bracteosa*, *Ligusticum purpureum*, *Anemone occidentalis*, *Erigeron salsuginosus*, and *Potentilla flabellifolia*. Localized seep areas on these otherwise dry slopes support such species as *Phyllodoce empetriformis*, *Veratrum viridum*, and *Valeriana sitchensis*.

Two closely related heather communities occupy the moister and cooler sites, such as ridgetops and protected east-facing slopes. These are the *Phyllodoce empetriformis*/*Lupinus latifolius*, and *Phyllodoce empetriformis*/*Vaccinium deliciosum* communities. Some of the dominant species in the *Phyllodoce*/*Lupinus* type are *Phyllodoce empetriformis*, *Cassiope mertensiana*, *Lupinus latifolius*, *Carex spectabilis*, and *Lycopodium* sp. Species characteristic of the *Phyllodoce*/*Vaccinium* type include *Phyllodoce empetriformis*, *Cassiope mertensiana*, *Vaccinium deliciosum*, *Lupinus latifolius*, and *Antennaria lanata*.

Snowbed communities are found at highest elevations in those localized areas where snowbanks persist until late in the growing season. Generally these sites are easily recog-

nized by the overwhelming dominance of *Carex nigricans*.

In general, *Phyllodoce* and related cooler, moister subalpine community types are most common at the head of the west branch of Butter Creek (e.g., around Cliff Lake) and least common at the head of the east branch below Pinnacle Peak. The *Festuca*-types are distributed in a reverse fashion, being most abundant on the slopes below Pinnacle Peak and extending toward Unicorn Peak.

Meadow-associated or timberline tree species have already been mentioned. None are known to invade the *Festuca*-dominated communities to any extent. However, both subalpine fir and mountain hemlock have invaded the *Phyllodoce* communities, a phenomenon commonly encountered in the Cascade Range and believed related to climatic fluctuations (Franklin et al. 1971).

A tentative list of mammals believed to inhabit the natural area as residents or transients is provided in table BU-1. Important resident birds include blue grouse (*Dendragapus obscurus*), Franklin's grouse (*Cathartes canadensis*), white-tailed ptarmigan (*Lagopus leucurus*), gray jays (*Perisoreus canadensis*), and Clark's nutcrackers (*Nucifraga columbiana*), the last named an important vector for the distribution of whitebark pine seeds. A bird checklist and a mammalogical guidebook (Potts and Grater 1949) for Mount Rainier National Park are available at the Park headquarters.

HISTORY OF DISTURBANCE

Human disturbance in the tract is essentially absent except in a very small area near the terminus of the Pinnacle Peak trail. South of the saddle where it terminates, visitors have produced numerous trails, campfire spots, and patches of trampled vegetation.

Perhaps the most important natural disturbances are the avalanches which repeatedly plunge down some of the more precipitous slopes and the oversteepened headwater channels of Butter Creek (fig. BU-3). There is abundant evidence that avalanching is probably the single most impor-

³ Data on subalpine meadows were in personal communication from Mr. Jan Henderson, Department of Botany, Oregon State University, Corvallis.

tant factor in controlling forest composition and age in the natural area.

RESEARCH

The Butter Creek Research Natural Area is currently being used as a sampling site in a study of alpine and subalpine meadow vegetation of Mount Rainier National Park.⁴

The natural area offers innumerable opportunities for ecological research on the communities, plants, and animals of subalpine regions in the Cascade Range. Its size makes it suitable for many types of research activities not possible in smaller tracts, such as studies of larger-sized animals. Furthermore, it provides a complete mosaic of subalpine communities rather than an isolated representation of only one. The great range in elevation makes it possible to study relationships over broad environmental and community gradients, from old-growth true fir-western hemlock stands to snowbed communities situated 760 m. (2,500 ft.) above. In addition, it offers an unparalleled opportunity to study succession following avalanching because of the

wide range in age and abundance of avalanche tracks which are present. Finally, the western and eastern parts of the natural area have sharply contrasting bedrock, making possible comparative studies of communities on intrusive and extrusive igneous rock types.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — special 15' x 25' Mount Rainier National Park, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955 and, for the southern third of the area, the 15' Packwood, Washington quadrangle, scale 1:62,500, issued in 1962; and *geology* — *Geologic Map and Sections of Mount Rainier National Park, Washington*, scale 1:62,500 (Fiske, Hopson, and Waters 1963), *Surficial Geology of Mount Rainier National Park, Washington*, scale 1:48,000 (Crandell 1969a), and *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). The Superintendent (Mount Rainier National Park, Longmire, Washington) can provide details on the most recent aerial photograph and type map coverage for the area.

⁴ Research by Mr. Jan Henderson, Department of Botany, Oregon State University, Corvallis.

Order	Scientific name	Common name
Insectivora	<i>Neurotrichus gibbsi</i>	shrew mole
	<i>Scapanus orarius</i>	coast mole
	<i>Scapanus townsendi</i>	Townsend mole
	<i>Sorex cinereus</i>	masked shrew
	<i>Sorex obscurus</i>	dusky shrew
	<i>Sorex palustris</i>	northern water shrew
	<i>Sorex trowbridgii</i>	Trowbridge shrew
	<i>Sorex vagrans</i>	wandering shrew
	<i>Eptesicus fuscus</i>	big brown bat
	<i>Lasionycteris noctivagans</i>	silver-haired bat
Chiroptera	<i>Lasiurus cinereus</i>	hoary bat
	<i>Myotis californicus</i>	California myotis
	<i>Myotis evotis</i>	long-eared myotis
	<i>Myotis lucifugus</i>	little brown myotis
	<i>Myotis volans</i>	long-legged myotis
	<i>Myotis yumanensis</i>	Yuma myotis
	<i>Lepus americanus</i>	snowshoe hare
	<i>Ochotona princeps</i>	pika
	<i>Aplodontia rufa</i>	mountain beaver
	<i>Castor canadensis</i>	beaver
Rodentia	<i>Clethrionomys gapperi</i>	Gapper red-backed vole
	<i>Erithizon dorsatum</i>	porcupine
	<i>Eutamias amoenus</i>	yellow-pine chipmunk
	<i>Eutamias townsendi</i>	Townsend chipmunk
	<i>Glaucomys sabrinus</i>	northern flying squirrel
	<i>Marmota caligata</i>	hoary marmot
	<i>Microtus longicaudus</i>	long-tailed vole
	<i>Microtus oregoni</i>	Oregon or creeping vole
	<i>Microtus richardsoni</i>	Richardson vole
	<i>Neotoma cinerea</i>	bushy-tailed wood rat
	<i>Peromyscus maniculatus</i>	deer mouse
	<i>Phenacomys intermedius</i>	heather vole
	<i>Spermophilus saturatus</i>	Cascades mantled ground squirrel
	<i>Tamiasciurus douglasi</i>	chickaree
	<i>Thomomys talpoides</i>	northern pocket gopher
	<i>Zapus princeps</i>	western jumping mouse
	<i>Canis latrans</i>	coyote
	<i>Felis concolor</i>	mountain lion or cougar
	<i>Lutra canadensis</i>	river otter
	<i>Lynx rufus</i>	bobcat
Carnivora	<i>Martes americana</i>	marten
	<i>Mustela erminea</i>	short-tailed weasel or ermine
	<i>Mustela frenata</i>	long-tailed weasel
	<i>Mustela vison</i>	mink
	<i>Spilogale putorius</i>	spotted skunk or civet cat
	<i>Ursus americanus</i>	black bear
	<i>Vulpes fulva</i>	red fox
	<i>Cervus canadensis</i>	wapiti or elk
	<i>Odocoileus h. columbianus</i>	black-tailed deer
	<i>Oreamnos americanus</i>	mountain goat
Artiodactyla

CANYON CREEK RESEARCH NATURAL AREA¹

Virgin ponderosa pine/pinegrass
stands in the Blue Mountains of
northeastern Oregon.

The Canyon Creek Research Natural Area was established August 2, 1960, as an example of virgin ponderosa pine (*Pinus ponderosa*) stands which are important in the Blue Mountains of central and northeastern Oregon. The 284-ha. (700-acre) tract is located in Grant County, Oregon, and is administered by the Bear Valley Ranger District (John Day, Oregon), Malheur National Forest. Unfenced, topographic boundaries give it an irregular shape (fig. CC-1). It occupies portions of sections 3, 4, 9, and 10, T. 15 S., R. 32 E., Willamette meridian. It lies at 44°17' N. latitude and 119°52' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is rather difficult because the nearest road terminates approximately 2.5 km. (1.5 miles) from the tract at a privately owned ranch. Directions should be obtained from the Bear Valley District Ranger together with a letter of introduction to the ranch owner. The rancher is most helpful when he knows a person has business on National Forest land, and he can give specific directions for following the correct jeep trail across his property. Public accommodations are available in Canyon City, 19 km. (12 miles) north on U.S. Highway 395 or at Wickiup Camp 10 km. (6 miles) south. Primitive camps are located

¹ Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

along Canyon Creek adjacent to the natural area; however, all stream water on livestock range is a potential source of typhoid fever and should be boiled.

ENVIRONMENT

The Canyon Creek Research Natural Area varies from 1,433- to 1,798-m. (4,700- to 5,900-ft.) elevation. It occupies a topographically gentle, southerly facing enclosed basin which rises from Canyon Creek to moderately steep ridges on the northern and western edges. Slope aspects are east, south, and west.

The natural area contains both granitic and andesitic parent rocks and some volcanic ash deposits on its upper slopes. It apparently straddles the contact between Strawberry Mountain granitics and serpentines and some of the many andesitic and basaltic flows characteristic of the Blue Mountains.

A modified continental climate prevails with cool, moist, partly cloudy winters and warm, dry, cloudless summers. Precipitation is moderate and seasonal, usually occurring as snow. Climatic data from Seneca, 16 km. (10 miles) southwest in a rain shadow valley, is as follows (U.S. Weather Bureau 1965):

Mean annual temperature4.7°C. (40.5°F.)
Mean January temperature-4.7°C. (23.6°F.)
Mean July temperature15.8°C. (60.4°F.)
Mean January minimum temperature-13.9°C. (7.0°F.)
Mean July maximum temperature28.8°C. (83.9°F.)
Average annual precipitation304 mm. (11.95 in.)
June through August precipitation40 mm. (1.59 in.)
Average annual snowfall177 cm. (69.8 in.)

Soils are variable. At lower elevations, residual and colluvial soils from granite are present in small areas. Generally, the upper slopes are covered by volcanic ash soils with buried residual profiles from andesite or granite. They may be broadly classed as Gray Wooded under forest cover and Regosols under juniper and bunchgrasses.

BIOTA

All forested stands in the area are dominated by ponderosa pine and are classed as SAF cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954). They apparently fit either Küchler's (1964) Types 10 or 11, Ponderosa Shrub Forest or Western Ponderosa Forest. Area and volume by forest composition (based on volume) are as follows:

Stand composition	Volume/unit area		Area	
	Cu. m./ha.	Bd. ft./ acre	Ha.	Acres
Ponderosa pine	196	14,000	158	390
Ponderosa pine (80%), western larch (10%), Douglas-fir (5%), grand fir (5%)	70	5,000	71	175
Ponderosa pine (90%), Douglas-fir (5%), grand fir (5%)	168	12,000	30	75
Ponderosa pine	42	3,000	4	10
Total Forested Area			264	650

There are, in addition, 20 ha. (50 acres) of nonforested communities covered by grass and brush.

Ponderosa pine clearly dominates the forest. With increasing elevation Douglas-fir (*Pseudotsuga menziesii*) and grand fir (*Abies grandis*) both increasingly dominate the understory as reproduction, suggesting pine is not climax over the entire area (fig. CC-2). Hall (1967) has suggested that the *Pinus ponderosa*/*Calamagrostis rubescens* community is generally successional to a grand fir-dominated community. Since grand fir seed sources are located at higher elevations and west of the tract, distribution of fir reproduction may be associated more with seed source than elevation.

Ground vegetation is dominated by pinegrass (*Calamagrostis rubescens*) with such associated species as elk sedge (*Carex geyeri*), *Fragaria* spp., *Lupinus caudatus*, *Hieracium scouleri*, *Arnica cordifolia*, *Ceanothus velutinus*, and *Vaccinium scoparium* (fig. CC-2). To a large extent, *Ceanothus velutinus* is decadent and dead. It seems to have deteriorated due to natural causes in the absence of conditions suitable for natural seed germination, such as ground fire.

This *Pinus*/*Calamagrostis* community is the most important grazing type in the Blue Mountains, occupying more area than all other range types combined. Palatable species are pinegrass and elk sedge. Forage production averages 272 kg. per hectare (600 lb. per acre) under 40- to 50-percent tree cover. As fir reproduction increases, forage production decreases and species composition changes. With overgrazing, palatable plants tend to decrease and unpalatable forbs and annual grasses increase; such conditions are moderately common where livestock obtain water along Canyon Creek.

A few nonforest communities are present in the natural area. Most common is the *Juniperus occidentalis*/*Agropyron spicatum* Association on shallow soils. Other species commonly present are *Cercocarpus ledifolius*, Sandberg bluegrass (*Poa secunda*), cheatgrass brome (*Bromus tectorum*), elk sedge, *Crepis acuminata*, *Achillea millefolium*, *Berberis repens*, *Danthonia unispicata*, and *Koeleria cristata*. Some rock outcrops are occupied by *Ceanothus velutinus* associated with *Prunus emarginata*, *Salix scouleriana*, elk sedge, and *Poa pratensis*. A rather dense forest of Douglas-fir, western larch (*Larix occidentalis*), and *Vaccinium scoparium* is present along the dry creek and the east slope at the tract's western edge. Associated species are ponderosa pine, grand fir, *Osmorhiza chilensis*, *Salix scouleriana*, elk sedge, *Hieracium albiflorum*, and pinegrass. Tree cover approaches 90 percent.

Resident and transient mammals believed to occur on the natural area are listed in table CC-1. Mule deer (*Odocoileus hemionus hemionus*) commonly browse in the area. Rocky Mountain elk (*Cervus canadensis*) occasionally winter in and near the tract.

HISTORY OF DISTURBANCE

Fire scars are common on ponderosa pine. They indicate a long history of ground fires which occurred at 15- to 20-year intervals until 1910 when a fire control program was initiated. Presumably, these fires tended to maintain ponderosa pine and *Ceanothus velu-*

tinus and discourage reproduction of Douglas-fir and grand fir.

Sheep grazing was common in the area until 1946 when it was terminated. Current game use is moderate to high, resulting in moderate to severe hedging of palatable browse plants. This condition is expected to continue.

No other disturbance has been recorded since establishment.

RESEARCH

No research activities in the tract are known. Special research opportunities in the area include: (1) long-term study of natural forest succession since fire control; (2) evaluation of seed source in relation to distribution of fir reproduction; (3) effect of various soils and topography on biomass production under a rather homogeneous macroclimate; and (4) evaluation of game use on subordinate vegetation.

MAPS AND AERIAL PHOTOGRAPHS

The U.S. Geological Survey topographic map for the 15' John Day, Oregon quadrangle, scale 1:62,500, issued in 1939, covers the natural area. Either the District Ranger (Bear

Valley Ranger District) or Forest Supervisor (Malheur National Forest, John Day, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

CEDAR FLATS RESEARCH NATURAL AREA¹

Old-growth stands of western redcedar and Douglas-fir growing on valley bottom benches in the southwestern Washington Cascade Range.

Cedar Flats Research Natural Area was established on March 14, 1946, to exemplify the western redcedar (*Thuja plicata*) stands found on valley bottom habitats in the Washington Cascade Range. The 275-ha. (680-acre) tract is located in Skamania County, Washington, and is administered by the Lewis River Ranger District (Cougar, Washington), Gifford Pinchot National Forest. The tract occupies portions of sections 11, 12, and 13, T. 7 N., R. 6 E., Willamette meridian. Legal lines form the boundaries on the north, west, and south and the Muddy River forms the boundary on the east (fig. CF-1). It lies at at 45°06' N. latitude and 122°01' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located approximately 5 km. (3 miles) north of the Lewis River Ranger Station on Forest Road 125. The Lewis River Ranger Station is easiest to reach from the west via Woodland and Cougar, which are approximately 73 km. (46 miles) and 27 km. (17 miles) away on State Highway 503 and Forest Road N90. Forest Road 125 cuts through the northwestern part of the natural area providing easy access (fig. CF-1). An old trail traverses the area from north to south along the western

edge of section 12 and can be utilized for portions of its length. The southwestern quarter of the research natural area is presently least accessible.

The nearest commercial accommodations are in Woodland, Washington, or can sometimes be arranged in Cougar. There are several improved forest camps in the vicinity of the natural area along the Muddy River.

ENVIRONMENT

Most of the Cedar Flats Research Natural Area occupies a gently undulating series of benches along the Muddy River. The northwestern corner of the natural area (west of Forest Road 125) is located on moderately steep slopes at the foot of some mountain ridges. Elevations range from about 366 to 640 m. (1,200 to 2,000 ft.).

Bedrock in the natural area is composed of Oligocene-Miocene volcanic rocks such as andesite flow breccias and andesite (Huntting et al. 1961). The benches are, of course, composed mainly of deposited materials. The exact nature of these materials and their mode of origin is unknown, but alluvium, glacial outwash, and mudflows are probably included. There are also surficial deposits of various Pleistocene and/or Recent volcanic ash or pumice falls, some of the ejecta forming distinct layers. Samples collected from surfaces of a nearby mudflow suggest that materials from at least the St. Helens "W" and Mount Rainier "C" ash deposits are present (Crandell 1969).²

The climate is wet and cool. Precipitation is seasonal, peaking during winter months and reaching low levels during the summer period. There are no nearby weather stations for which published data are available; how-

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

² Personal communication from Dr. H. W. Smith, Agronomy Department, Washington State University, Pullman.

ever, unpublished records for the Lewis River Ranger Station, located approximately 5 km. (3 miles) south of the natural area, are on file there.

Soils within the natural area have not been carefully examined. Soil types belonging to the Brown Podzolic, Sols Bruns Acides, Alluvial, and Humic Gley great soils groups were encountered during the reconnaissance. Organic soils are associated with some of the swamp and marsh land habitat. Soil profiles within the natural area typically exhibit several primary or secondary depositions of Pleistocene and/or Recent volcanic ejecta.

BIOTA

Approximately 255 ha. (630 acres) of the natural area are occupied by forest and 20 ha. (50 acres) by nonforested communities. Areas by SAF cover types are as follows (Society of American Foresters 1954):

No.	Name	Area
230	Douglas-Fir — Western Hemlock ³	162 ha. (400 acres)
228	Western Redcedar	89 ha. (220 acres)
221	Red Alder	4 ha. (10 acres)

The area would include Kuchler's (1964) Types 2, Cedar-Hemlock-Douglas Fir Forest; and 25, Alder-Ash Forest. The area falls within the *Tsuga heterophylla* Zone of Franklin and Dyrness (1969).

The most abundant tree species within the natural area are western redcedar and Douglas-fir (*Pseudotsuga menziesii*). Other coniferous tree species present in lesser numbers are western hemlock (*Tsuga heterophylla*), Pacific silver fir (*Abies amabilis*), grand fir (*Abies grandis*), and western white pine (*Pinus monticola*). Hardwoods commonly encountered are red alder (*Alnus rubra*), big-leaf maple (*Acer macrophyllum*), and black cottonwood (*Populus trichocarpa*).

Stands of old-growth western redcedar and associated swamps and marshes are the key features of the natural area (fig. CF-2). These are located on higher benches in the center of

³ A portion of this area, particularly that occupied by younger stands, might be classified as SAF type 229, Pacific Douglas-Fir.

the tract near Forest Road 125 (fig. CF-1). The western redcedar range from 90- to 300-cm. (36- to 120-in.) d.b.h. (fig. CF-2) and reach heights in excess of 60 m. (200 ft.). Some individual areas of dense western redcedar trees, which were cruised at the time of the natural area establishment, contain timber volumes exceeding 2,800 cu. m. per ha. (200,000 bd. ft. per acre).

Acer circinatum and *Polystichum munitum* dominate the shrub and herb layers of most western redcedar stands (fig. CF-2). *Cornus nuttallii*, Pacific yew, (*Taxus brevifolia*), and bigleaf maple complete the list of common tall shrubs and small trees. *Oplopanax horridum* and *Berberis nervosa* are typical low shrubs. There is a rich selection of herbs such as *Achlys triphylla*, *Tiarella unifoliata*, *Blechnum spicant*, *Vancouveria hexandra*, and *Gymnocarpium dryopteris*.

A variety of swamp and marsh communities are associated with seasonally or continuously wet sites. They provide habitat for a rich collection of aquatic and semiaquatic plant species. Large areas of this type tend to be a mosaic of shrub- and herb-dominated stands with scattered stunted red alder and, perhaps, conifers on hummocks (fig. CF-2). The more common shrubs are *Salix* spp., *Spiraea* sp., *Rubus spectabilis*, *Cornus stolonifera*, *Pyrus rivularis*, *Prunus emarginata*, and *Acer circinatum*. Herb dominants include *Athyrium filix-femina*, *Carex obnupta*, *Scirpus microcarpus*, and *Lysichitum americanum*.

Stands dominated by Douglas-fir occupy the bulk of the natural area. These include both old-growth and second-growth age classes, the former surrounding the western redcedar type and blending with it at its edges. In these Douglas-fir-dominated stands, western hemlock and Pacific silver fir appear to be the climax species. Successional processes are particularly evident in the stands on the west and south where the Douglas-fir overstory is rapidly breaking up.

The Douglas-fir-dominated stands appear to occupy a wide range of environmental conditions judging by variations in understory composition. In the southwestern corner

of the natural area, *Gaultheria shallon*, *Acer circinatum*, *Berberis nervosa*, and *Achlys triphylla* are typical understory dominants. On other sites an herbaceous-dominated understory (e.g., *Polystichum munitum* and *Vancouveria hexandra*) suggest much more mesic and fertile conditions.

Wildlife make significant use of the natural area. It provides late fall and winter range for a herd of Roosevelt elk (*Cervus canadensis roosevelti*) and for deer (*Odocoileus hemionus columbianus*). In fact, these animals may be encountered in the area at almost any time of year and their grazing undoubtedly has a significant impact on the character of the plant communities. Black bear (*Ursus americanus*) also forage the swampy areas during the spring, and some may possibly hibernate on the natural area. Predators such as coyote (*Canis latrans*), cougar (*Felis concolor*), and bobcat (*Lynx rufus*) are occasional visitors, probably following the deer and elk. Other animals such as mink (*Lutreola lutreola*), river otter (*Lutra canadensis pacifica*), and beaver (*Castor canadensis*) inhabit areas along the Muddy River. A complete list of mammals believed to utilize the natural area is provided in table CF-1.

The variety of semiaquatic and terrestrial, forested and open areas, undoubtedly provide habitat for a variety of birds, reptiles, and amphibians.

RESEARCH

No research is presently known to be in progress on the natural area. Short-term studies would be extremely timely since a large portion of the natural area will be flooded if work proceeds on a proposed and licensed power dam on the Muddy River. Research opportunities include studies of: (1) the ecology of western redcedar and associated conifers; (2) patterns in community composition and structure in relation to environmental conditions; (3) effects of Roose-

velt elk on plant communities; and (4) relationships between small animal populations and plant communities over a range of terrestrial and semiaquatic habitats.

HISTORY OF DISTURBANCE

The only recent natural disturbances are those associated with the activity of the Muddy River along the eastern boundary. There is no evidence of recent wildfires within the natural area. The fire which gave rise to the second-growth Douglas-fir stands occurred at least 130 years ago.

Human disturbances are confined to roadsides and the margins of the natural area. Unfortunately, the forest stand on private land adjacent to the southern boundary of the natural area was clearcut about 1967; this has produced, and will continue to produce, some edge effects, exposing this boundary to windfall damage. Forest Road 125 has altered natural conditions in the northwestern corner of the natural area to an unknown degree, but it is located at the extreme western edges of the benches.

As mentioned, the area does lie partially within the reservoir area of Pacific Power and Light Company's Muddy River Dam project. It is not known whether the dam will be built or, if so, when.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Mount St. Helens, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956; and *geology* — *Geologic Maps of Washington*, scale 1:500,000 (Hunting et al. 1961). The District Ranger (Lewis River Ranger District) or Forest Supervisor (Gifford Pinchot National Forest, Vancouver, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

CHERRY CREEK RESEARCH NATURAL AREA¹

Old-growth Douglas-fir and western hemlock stands growing on slopes and ridgetops in the southwestern Oregon Coast Ranges.

The Cherry Creek Research Natural Area was established on February 4, 1965. It typifies virgin, old-growth Douglas-fir (*Pseudotsuga menziesii*)-western hemlock (*Tsuga heterophylla*) stands as they occur on sedimentary materials in the southwestern Oregon Coast Ranges. The 239-ha. (590-acre) tract is located in Coos County, Oregon, and is administered by the Coos Bay District (Coos Bay, Oregon), Bureau of Land Management (BLM). The natural area occupies portions of sections 17, 18, 19, and 20, T. 27 S., R. 10 W., Willamette meridian (fig. CH-1). It lies at 45°13' N. latitude and 123°56' W. longitude.

ACCESS AND ACCOMMODATIONS

The normal approach to the natural area is from Coquille, to the south. Just west of the Coquille High School, turn north from State Highway 42 onto the Fairview-McKinley Road. At Fairview, 14.5 km. (9 miles) to the north, turn southeast (right) onto the Coos Bay Wagon Road. Follow this road to Cherry Creek Park (about 11 km. or 7 miles) and turn left on Cherry Creek County Road which later changes to the B.L.M. Cherry Creek Access Road (27-11-27.0). Follow it for 9.5 km. (6 miles) to the Big Tree Recreational

Site at the edge of the natural area. The vicinity of the natural area can also be reached via the BLM Middle Creek Access Road (27-11-29.0) and Burnt Mountain Road (27-11-12.0). To approach the north side of the natural area in this way, turn onto the Middle Creek Access Road about 6 km. (4 miles) east of Fairview.

There are no roads or trails within the main body of the natural area. Access is by cross-country travel.

The nearest commercial accommodations are in Coquille and Coos Bay, approximately 35 km. (22 miles) and 50 km. (31 miles) away, respectively. There are several improved forest camps in the vicinity, the most convenient being located on Middle Creek.

ENVIRONMENT

The Cherry Creek Research Natural Area occupies complex ridge and valley topography bounding a portion of Cherry Creek. Slopes are generally moderate to steep on the middle and lower slopes and gentle to moderate along the ridgetops (fig. CH-1). Elevations range from about 207 m. (680 ft.) along Cherry Creek to 451 m. (1,480 ft.) in the northwestern corner of the natural area. The topography is very complex and dissected.

Sedimentary bedrock underlies the entire natural area. These sand and siltstones belong to the Tyee formation of Middle Eocene Age (Pech 1961).

The climate is wet and mild. Precipitation is seasonal, with a peak in January and December and a minimum in July and August. The summer drought period is more pronounced than in northern Oregon and Washington coastal mountains. The following climatic data are from the closest weather station at Sitkum located about 5 km. (3 miles) to the southeast (U.S. Weather Bureau 1965):

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

Mean annual temperature 11.1°C. (52.0°F.)
 Mean January temperature 4.2°C. (40.6°F.)
 Mean July temperature 17.2°C. (63.0°F.)
 Mean January minimum
 temperature 0.8°C. (33.5°F.)
 Mean July maximum temperature . . 25.1°C. (77.2°F.)
 Average annual precipitation . . . 2,035 mm. (80.11 in.)
 June through August
 precipitation 82 mm. (3.21 in.)

A soil survey for the area is not available, but most soils tend toward relatively deep, Reddish-Brown Lateritics developed in colluvium and residuum from silt and sandstones. Surface (A1) horizons are typically dark brown in color and the B2 horizon has a clay-loam texture and fine to very fine, sub-angular, blocky structure. Depth to bedrock (R horizon) is typically from 100 to over 150 cm. (40 to 60 in.). A horizons typically average about 20 cm. (8 in.) in thickness and B horizons 75 to 90 cm. (30 to 35 in.).

BIOTA

All 239 ha. (590 acres) of the Cherry Creek Research Natural Area are classified as SAF cover type 230, Douglas-Fir — Western Hemlock (Society of American Foresters 1954). The area falls within Küchler's (1964) Type 2 (Cedar-Hemlock-Douglas Fir Forest) and the *Tsuga heterophylla* Zone of Franklin and Dyrness (1969).

Douglas-fir and western hemlock dominate the natural area. The average age of the Douglas-fir is not known, but it is believed to be in excess of 300 years. Old-growth Douglas-firs average 125- to 175-cm. (50- to 70-in.) d.b.h. The maximum recorded size is 294-cm. (116-in.) d.b.h. and 86.9 m. (285 ft.) high at over 600 years of age. Western hemlock typically average 75- to 100-cm. (30- to 40-in.) d.b.h. and are somewhat younger in age than associated Douglas-fir. Other tree species present on the natural area include western redcedar (*Thuja plicata*) and tanoak (*Lithocarpus densiflora*), with bigleaf maple (*Acer macrophyllum*) and California-laurel (*Umbellularia californica*) common in stream-side areas (fig. CH-2).

The climax tree species on the natural area clearly appears to be western hemlock. Hem-

lock seedlings and saplings are more abundant than those of any other coniferous species. In some areas sprout and seedling reproduction of tanoak is also common, suggesting it may also be a climax species. Very little reproduction of Douglas-fir or western redcedar is present anywhere on the natural area.

Most of the forest communities on the natural area are assignable to one of the associations recognized by Bailey (1966) in a study of nearby old-growth forests. The communities on middle and lower slopes and on broad mesic ridgetops appear to belong to the *Tsuga heterophylla*/Polystichum munitum — *Oxalis oregana* Association. The understory is dominated by a dense cover of *Polystichum munitum*, with many other associated herbs such as *Oxalis oregana*, *Tiarella trifoliata*, *Adiantum pedatum*, *Athyrium filix-femina*, *Blechnum spicant*, *Montia sibirica*, and *Galium triflorum* (fig. CH-2). The shrubby layer is poorly developed, being confined to *Berberis nervosa* and scattered cover of vine maple (*Acer circinatum*), *Vaccinium parvifolium*, *V. ovatum*, and *Rhododendron macrophyllum*. A community related to Bailey's (1966) *Tsuga heterophylla* — *Pseudotsuga menziesii*/ *Rhododendron macrophyllum*/ *Berberis nervosa* Association occurs on some upper side slopes and narrow ridgetops, particularly those with a southerly or westerly aspect. Shrubs such as *Rhododendron macrophyllum* and *Berberis nervosa* and small hardwoods such as tanoak and golden chinkapin (*Castanopsis chrysophylla*) are much more conspicuous in communities of this type. Conversely, the herbaceous layer is much more poorly developed.

Resident and transient mammals believed to occur within the natural area are listed in table CH-1. The most important mammal, the Roosevelt elk (*Cervus canadensis roosevelti*), utilizes the area and its surroundings heavily. Browsing and trampling by elk is undoubtedly a major influence upon the character of the understory communities within the forest stands and helps account for their relatively open nature. Elk trails provide some of the easiest means for travel through

the area. Heaviest elk use appears to be the broad ridge tops in the center and southern half of the natural area.

There are several miles of live stream course within the natural area. These streams and the streamside areas provide specialized habitats for a variety of flora and fauna. A few minor tributaries of Cherry Creek are located entirely within the natural area and support both steelhead (*Salmo gairdneri*) and sea-run cutthroat trout (*Salmo clarki*).

HISTORY OF DISTURBANCE

Major human influences upon the area are related to the road construction and clearcut logging operations adjacent to the natural area boundaries. Burnt Mountain Road (27-11-12.0), which is located along the northern edge of the natural area, is probably most important in this regard. Construction and maintenance of this road has influenced the slopes below, which are within the natural area. A picnic site and short nature trail have been developed along the western edge of the natural area (Big Tree Site). There is relatively little visitor use of the natural area core because of the lack of trails.

There is no evidence that wildfires have occurred within the natural area for at least 190 years. Nor is there evidence of recent catastrophic damage by windthrow or bark beetles.

RESEARCH

No research studies are presently known to be in progress on the Cherry Creek Research Natural Area. Some data on community structure and limited plant collections have been obtained by Forest Service personnel. The natural area provides an excellent site for studying the old-growth coniferous forest that once typified a large portion of Oregon's Coast Ranges and for studying the effect of Roosevelt elk upon the structure and composition of such communities.

MAPS AND AERIAL PHOTOGRAPHS

Maps applicable to the natural area include:

Topography — 15' Sitkum, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). The District Manager (Coos Bay District, Bureau of Land Management, Coos Bay, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

COQUILLE RIVER FALLS RESEARCH NATURAL AREA¹

Port-Orford-cedar and Douglas-fir
growing in a rugged mountain can-
yon in the southwestern Oregon
Coast Ranges.

The Coquille River Falls Research Natural Area was established on January 31, 1945, to provide examples of virgin old-growth Port-Orford-cedar (*Chamaecyparis lawsoniana*) stands. The 202-ha. (500-acre) tract is located in Coos County, Oregon, and is administered by the Powers Ranger District, Powers, Oregon (Siskiyou National Forest). The natural area occupies portions of sections 16, 17, 18, 20, and 21, T. 33 S., R. 11 W., Willamette meridian. The natural area is bounded by Forest Road 333 on the northwest, by Forest Road 321 on the west, south, and east, and by the center line of sections 16 and 17 on the north (fig. CO-1). It lies at 42°44' N. latitude and 124°03' W. longitude.

ACCESS AND ACCOMMODATIONS

Primary access is via State Highway 242 and Powers, which lies 29 km. (18 miles) south of State Highway 42 and about 34 and 48 km. (21 and 30 miles) from Myrtle Point and Coquille, respectively. To reach the natural area, travel south from Powers on Forest Road 333 for about 33 km. (20 miles) to the bridge across the South Fork of the Coquille River. This bridge is located on the northwest

boundary of the tract. For the next several kilometers Roads 333 and 321 bound the natural area.

Generally, cross-country travel is necessary within the natural area. Immediately east of Squaw Creek an unmarked trail leads from Road 321 down to Coquille River Falls. The upper- and mid-slopes of the natural area on the south side of the river are reasonably accessible from the road. Access to the lower slopes and area of the river is difficult, however. The best way to reach the latter is from the northwestern corner of the natural area entering just north of the bridge where Road 333 crosses the South Fork of the Coquille River.

The nearest commercial accommodations are in Powers, Myrtle Point, Coquille, and Gold Beach; however, there are several improved forest camps along Forest Road 333 in the vicinity of the natural area: Daphne Grove, Myrtle Grove, and Boundary.

ENVIRONMENT

The Coquille River Falls Research Natural Area occupies a topographically rugged canyon area. Except for a few benches along Road 321, slopes are moderate to very steep. Cliffs and rock outcrops are occasionally encountered and are very common along the river itself (fig. CO-2). The South Fork of the Coquille River and numerous other streams such as Squaw and Drowned Out Creek flow through the southern part of the natural area. Spring and seep areas are also common. Elevations within the natural area range from 305 to 760 m. (1,000 to 2,500 ft.).

The natural area is relatively simple geologically (Diller 1903, Wells 1955, and Peck 1961). Bedrock is composed of sedimentary materials, primarily sand and siltstones, belonging to the Tyee formation of Eocene age.

The climate is wet and mild. Precipitation

¹ Description prepared by Dr. J. F. Franklin and Dr. C. T. Dyrness, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

is seasonal, with a peak in January and December and a minimum in July and August. The summer drought period is more pronounced than in the northern Oregon and Washington coastal mountains. The following climatic data are from the closest weather station at Powers (U.S. Weather Bureau 1965):

Mean annual temperature	12.0°C. (53.6°F.)
Mean January temperature	6.6°C. (43.8°F.)
Mean July temperature	17.6°C. (63.6°F.)
Mean January minimum temperature	1.6°C. (34.8°F.)
Mean July maximum temperature ..	25.0°C. (77.0°F.)
Average annual precipitation ...	1,535 mm. (60.44 in.)
June through August precipitation	56 mm. (2.19 in.)

Since Powers is about 150 m. (500 ft.) lower in elevation, temperatures are lower and precipitation higher on the natural area; isohyetal maps (Oregon State Water Resources Board 1959) indicate 2,500 to 2,800 mm. (100 to 110 in.) annual precipitation.

Soils vary greatly in depth throughout the area. The profiles typically are not strongly developed. On better sites, soils tend toward Reddish-Brown Lateritics with 5- to 10-cm. (2- to 4- in.) thick A1 horizons. These profiles are typically developed in relatively deep colluvial deposits. Soils are generally much shallower on the slopes north of the Coquille River, where either Brown Podzolic or Lithosolic types may be encountered.

BIOTA

All of the natural area is classed as SAF cover type 231, Port-Orford-Cedar-Douglas-Fir (Society of American Foresters 1954). The area falls within Kuchler's (1964) Type 2, Cedar-Hemlock-Douglas Fir Forest, and the *Tsuga heterophylla* Zone of Franklin and Dyrness (1969).

Port-Orford-cedar and Douglas-fir (*Pseudotsuga menziesii*) are the most important tree species within the natural area composing approximately 22 percent and 69 percent of the total timber volume (fig. CO-2). There are particularly fine specimens of Port-Orford-cedar on the benches along Forest Road 321 (fig. CO-2); these trees attain diameters in

excess of 130 cm. (50 in.) b.h. and heights in excess of 60 m. (200 ft.) Western hemlock (*Tsuga heterophylla*), grand fir (*Abies grandis*), sugar pine (*Pinus lambertiana*), and Pacific yew (*Taxus brevifolia*) are other coniferous tree species found within the tract. Hardwoods are well represented though not necessary in the highest canopy levels. These include red alder (*Alnus rubra*), tanoak (*Lithocarpus densiflorus*), golden chinkapin (*Castanopsis chrysophylla*), and Pacific madrone (*Arbutus menziesii*).

General successional trends are toward replacement of Douglas-fir and Port-Orford-cedar by western hemlock. Hemlock seedlings and saplings are the most abundant in mature forest stands, while those of grand fir and Port-Orford-cedar are relatively uncommon or absent. However, sprout and seedling reproduction of tanoak is as abundant as or more so than that of western hemlock in some stands, suggesting it may also be a major climax species.

There are a variety of distinctive forest communities found within the natural area. Most conspicuous are the old-growth coniferous stands dominated by Port-Orford-cedar and Douglas-fir which are concentrated south of the Coquille River. *Polystichum munitum* dominates the understory on moist benches as well as on well watered slopes or in seep areas. Typical associated species are *Oxalis oregana*, *Berberis nervosa*, *Galium triflorum*, *Viola sempervirens*, *Hierchloe occidentalis*, and *Trillium ovatum*. Shrubs commonly encountered on such sites are *Vaccinium ovatum*, tanoak, and *Gaultheria shallon*.

Other old-growth stands, e.g., those found on drier sites, may have a dense understory of shrubs and small trees such as *Rhododendron macrophyllum*, *Vaccinium parvifolium*, *P. ovatum*, tanoak, golden chinkapin, *Gaultheria shallon*, and *Berberis nervosa*. Herbaceous species include many of those found on moister sites (e.g., *Polystichum munitum*), but coverage of the herbaceous layer is typically much lower.

Younger, second-growth stands growing on relatively poor sites typify the natural area north of the Coquille River. Douglas-fir

and Port-Orford-cedar are the most important coniferous tree species present, but sugar pine is also found in these stands. Hardwoods, such as golden chinkapin, tanoak, and Pacific madrone, are much more important than in the older stands, and the understory is dominated by shrubs such as *Rhododendron macrophyllum*, *Gaultheria shallon*, and *Berberis nervosa*.

There are some small areas of *Alnus rubra*/*Polystichum munitum* communities scattered through the southern half of the natural area (fig. CO-2). There is relatively little evidence of successional direction in these stands; reproduction is lacking in almost all species.

Mammals believed to reside or occur as transients within the natural area are listed in table CO-1. A variety of amphibians, such as frogs and salamanders, are associated with the streams and seep areas. *Ensatina* (*Ensatina eschscholtzi*), Pacific giant salamander (*Dicamptodon ensatus*), and clouded salamanders (*Aneides ferreus*) have been collected within the natural area.

Specialized habitats within the Coquille River Falls Research Natural Area include the stream and stream side areas and the rock cliffs found along the South Fork of the Coquille River (fig. CO-2).

HISTORY OF DISTURBANCE

The most serious disruptive influence has been the recent invasion of an exotic root pathogen, *Phytophthora lateralis*, which is invariably fatal to Port-Orford-cedar. In 1966 the pathogen was not known to be present in the natural area and there were no cedar dying at that time. By 1968 dying Port-Orford-cedar were common along Road 321 and extended down the drainages north of this road. This follows the typical pattern of invasion for this pathogen. In 1970 nearly half (47 percent) of the Port-Orford-cedar volume was in snags and down trees in contrast to 16 percent in the nearby, but not yet infested, Port Orford Cedar Research Natural Area.² It is expected that most of the stands

² Unpublished cruise data on file at Powers Ranger Station, Siskiyou National Forest, Powers, Oregon.

on the south side of the South Fork of the Coquille River will eventually become infected.

Severe fire scars are present on the old Port-Orford-cedar and Douglas-fir (fig. CO-2). These scars and the scattering of youthful red alder stands are evidence of periodic wild-fires in the area prior to the establishment of fire control programs. None appear to have occurred in recent years.

Human disturbance of the area is confined to the road and trail side areas and to the vicinity of Coquille River Falls which receives moderate visitor use.

RESEARCH

There are no research studies in progress on the Coquille River Falls Research Natural Area. Some data on community structure and limited plant collections have been obtained by Forest Service personnel.

This natural area compliments the larger Port Orford Cedar Research Natural Area located about 5 km. (2 miles) to the northwest. Research opportunities include studies of: (1) variation in forest composition, structure, and dynamics under contrasting environmental and stand conditions; and (2) fauna and flora associated with rock outcrops and cliffs found in a major river canyon. The recent and rapidly progressing invasion of the area by *Phytophthora lateralis* makes studies of the communities and the ecological impacts of the pathogen upon them especially timely.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Agness, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1954; and *geology* — *Description of the Port Orford Quadrangle*, scale 1:250,000 (Diller 1903), *Preliminary Geologic Map of Southwestern Oregon*. . . , scale 1:250,000 (Wells 1955), and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). DIAMOND POINT RESEARCH NATURAL AREA¹

**Second-growth western hemlock,
Sitka spruce, and red alder growing
on an island in a coastal estuary in
southwestern Washington.**

The Diamond Point Research Natural Area was established as an example of second-growth Sitka spruce (*Picea sitchensis*) - western hemlock (*Tsuga heterophylla*) forest growing on a peninsula in a coastal estuary. The 36-ha. (88-acre) tract is located in Pacific County, Washington, and is administered by the Bureau of Sport Fisheries and Wildlife. It is located at the northern tip of Long Island in Willapa Bay and is part of Willapa National Wildlife Refuge (Ilwaco, Washington). The natural area occupies a portion of the northern half of section 25, T. 12 N., R. 11 W., Willamette meridian (fig. DP-1). It lies at 46°29' N. latitude and 123°59' W. longitude.

ACCESS AND ACCOMMODATIONS

Access to the vicinity is via U.S. Highway 101 to headquarters of the Willapa National Wildlife Refuge, located approximately 21 km. (13 miles) north of Ilwaco, Washington. The headquarters site is opposite the southern end of Long Island, and the Bureau maintains a boat and docking facilities for the 0.5-km. (0.3-mile) trip to the island. On the island there is a limited logging road system which comes within 0.8 km. (0.5 mile) of the southern boundary of the natural area. The sole

means of transportation on Long Island is a jeep maintained by the Bureau of Sport Fisheries and Wildlife. An alternative approach is by boat, going from the headquarters dock directly to the natural area — a trip of perhaps 10 to 14 km. (6 to 8 miles). There are no trails in the natural area, so access is by cross-country hiking or walking along the shoreline at low tide.

A wide range of commercial accommodations are available at Ilwaco, Seaview, and Long Beach, about 19 to 22 km. (12 to 14 miles) south of Willapa National Wildlife Refuge headquarters. There are seven public campgrounds on Long Island, all of them reached by boat. One of them — Diamond Point Campground — is actually located within the boundaries of the natural area.

ENVIRONMENT

Topography on the Diamond Point Research Natural Area is, for the most part, composed of moderate slopes along several broad ridges which are interrupted by short drainage channels. There are small areas of steeper slopes, notably along the northwest-facing shore where slopes plunge abruptly to the bay. Elevations range from sea level to just over 30 m. (100 ft.). The natural area is bounded on the east, north, and west by approximately 1.2 km. (3/4 mile) of shoreline.

Geologically the Diamond Point Research Natural Area is made up of marine terraces of Pliocene to Pleistocene age (Hunting et al. 1961). These terraces are characterized by alternating beds of unconsolidated to partly consolidated silt, clay, and sand.

The area has a pronounced cool and wet marine climate. Although a large proportion of the total annual precipitation occurs during the winter, there is sufficient rainfall and foggy weather during the summer to maintain relatively high levels of soil moisture. Not only does fog reduce potential evapo-

¹ Description prepared by Dr. C. T. Dyrness, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

transpiration, it also results in moisture accretion by "fog drip" from tree crowns. Temperature range throughout the year is minimal; winter temperatures are relatively mild and summers tend to be cool. The following climatic data are from the Willapa Harbor Climatic Station (U.S. Weather Bureau 1965):

Mean annual temperature 10.6°C. (51.1°F.)
 Mean January temperature 4.6°C. (40.3°F.)
 Mean July temperature 16.3°C. (61.4°F.)
 Mean January minimum
 temperature 1.2°C. (34.1°F.)
 Mean July maximum temperature .. 22.0°C. (71.5°F.)
 Average annual precipitation . . . 2,156 mm. (84.87 in.)
 June through August
 precipitation 149 mm. (5.87 in.)

Even though the Willapa Harbor Climatic Station is located about 26 km. (16 miles) northeast of the natural area, climatic conditions should be roughly the same at both locations.

Soils information for the area is from a limited number of observations. Apparently most soils are Sols Bruns Acides with textural profiles largely inherited directly from the stratified parent material. Forest floor layers (01 and 02 horizons) are generally thick, ranging from 13 to 25 cm. (6 to 10 in.) in depth. These layers often contain a large proportion of the total root mass. The surface mineral horizon, averaging about 8 cm. (3 in.) in thickness, consists of very dark brown to black silt loam and obviously contains a large amount of incorporated organic matter. This is underlain by a dark brown, silt loam to silty clay loam horizon which ranges from 13 to 25 cm. (6 to 10 in.) in thickness. The subsoil material may vary from a partially indurated sand to a sticky clay, depending on parent material stratigraphy. In some locations the subsoil shows pronounced mottling, indicating impeded internal drainage.

BIOTA

Estimated areas by SAF cover types (Society of American Foresters 1954) are:

No.	Name	Area
225	Sitka Spruce —	
	Western Hemlock	18 ha. (45 acres)
224	Western Hemlock	10 ha. (25 acres)
221	Red Alder	7 ha. (18 acres)

The area falls within Küchler's (1964) Type 1, Spruce-Cedar-Hemlock Forest, and the *Picea sitchensis* Zone of Franklin and Dyrness (1969).

There are only three tree species of any importance in the natural area: red alder (*Alnus rubra*), Sitka spruce, and western hemlock. Most of the stands appear to be approximately 70 to 80 years old, having resulted from logging of the area some time near the turn of the century. Composition of coniferous stands ranges from Sitka spruce, with minor amounts of hemlock on north and west facing slopes, to pure stands of western hemlock on ridgetops and south slopes. Tree regeneration under spruce-hemlock stands usually consists of scattered stems of both spruce and hemlock. Red alder also occasionally occurs in small openings. In stands where hemlock is the dominant tree in the overstory, regeneration is dominantly western hemlock with very few Sitka spruce. Pure, even-aged stands of red alder occur in drainageways and in low areas along the shoreline.

Tree overstory coverage in coniferous stands varies from about 60 to 75 percent. In the denser alder stands it averages 90 to 100 percent. Typical western hemlock and Sitka spruce trees are from 30- to 46-cm. (12- to 18-in.) d.b.h., with the largest specimens ranging up to 91-cm. (36-in.) d.b.h.

There are two main understory community types in coniferous stands within the natural area: (1) the *Polystichum munitum* type found in moist areas where Sitka spruce is the dominant tree species, and (2) a *Gaultheria shallon* type generally associated with hemlock-dominated timber stands. The *Polystichum* community is characterized by only scattered shrub cover contributed mainly by *Vaccinium parvifolium*, *V. ovatum*, *Rhamnus purshiana*, *Sambucus melanocarpa*, and *Rubus spectabilis*. *Gaultheria shallon*, if present, is often restricted to rotten logs and stumps. The herb layer is dominated by a luxurious growth of *Polystichum munitum* which may cover as much as 80 percent of the ground surface. Other common herbaceous species include *Blechnum spicant*, *Athyrium filix-femina*, *Galium triflorum*, *Pyrola uni-*

flora, *Luzula parviflora*, *Maianthemum bifolium* var. *kamtschaticum*, *Lysichitum americanum*, *Dryopteris dilatata*, *Oxalis oregana*, *Tiarella trifoliata*, *Trillium ovatum*, and *Monotropa hypopitys*. A heavy growth of moss covers the ground in all coniferous stands. Average moss cover is generally 80 to 90 percent, with *Eurynchium oreganum* probably the most common species.

The *Gaultheria* community is dominated by large amounts of *Gaultheria shallon*, some of it up to 2 m. (6 ft.) in height. Other common shrubs are *Vaccinium parvifolium*, *V. ovatum*, *Rhamnus purshiana*, and *Menziesia ferruginea*. The herb layer is scattered and made up of species such as *Polystichum munitum*, *Blechnum spicant*, *Dryopteris dilatata*, *Polypodium scolieri* (both on the ground and as an epiphyte), *Galium triflorum*, *Luzula parviflora*, and *Osmorhiza nuda*.

The vegetation under pure stands of red alder in drainages and swampy swales is made up of the above mentioned ferns, *Lysichitum americanum*, *Montia sibirica*, *Carex* spp., *Cardamine* sp., *Melissa officinalis*, *Equisetum* sp., and a variety of other moisture-loving species. Several low-lying alder stands adjacent to the bay have an almost pure *Carex* understory which is unusually lush and dense (fig. DP-2).

Mammals believed to utilize the area as either residents or transient visitors are listed in table DP-1. Birds frequenting the area include band-tailed pigeons (*Columba fasciata*), bluegrouse (*Dendragapus obscurus*), and ruffed grouse (*Bonasa umbellus*).

HISTORY OF DISTURBANCE

As previously mentioned, the area was logged some 70 to 80 years ago. Since then, there appears to have been very little additional disturbance by man. There is a small,

primitive campground (Diamond Point Campground) reached only by water near the northwestern corner of the area, but so far the user-related disturbances do not extend very far inland. All of Long Island is a big-game, bow-hunting area, and hunters undoubtedly pass through the area, but effects of this use appear negligible. There is, however, considerable evidence of heavy browsing of shrubs and ferns by deer and elk in some of the more open stands.

In 1966 a clearcut logging operation came close to the southern boundary of the natural area. Because of the lack of natural area boundary markers, it is difficult to tell exactly how much of a buffer, if any, remains between the clearcut and the natural area.

RESEARCH

No research is currently being conducted in the area and, so far as is known, none has been conducted in the past. The natural area offers a good opportunity for studying the development of young second-growth stands of western hemlock, Sitka spruce, and red alder.

MAPS AND AERIAL PHOTOGRAPHS

Maps covering the natural area are: *Topography* — 15' Fort Columbia, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1938; 7 1/2' Long Island, Washington quadrangle, scale 1:31,250, issued by the U.S. Geological Survey in 1949; *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). The Refuge Manager of the Willapa National Wildlife Refuge (Ilwaco, Washington) can provide information on recent aerial photographs and maps.

GOLD LAKE BOG RESEARCH NATURAL AREA¹

**Subalpine bog communities and
flora and surrounding forest lands
near the crest of the Oregon Cascade
Range.**

The Gold Lake Bog Research Natural Area was established August 10, 1965, to preserve some prime subalpine bogs and several species of rare bog plants. The 188-ha. (463-acre) tract is located in Lane County, Oregon, and is administered by the Oak Ridge Ranger District (Oak Ridge, Oregon), Willamette National Forest. The natural area occupies most of the S1/2 S1/2 section 20 and N1/2 section 29, T. 22 S., R. 6 E., Willamette meridian. Legal lines provide most of the boundary except for the southeastern quarter, where the boundary follows Skyline Creek and Forest Trail 3681 (Maiden Peak Trail) for a portion of its length (fig. GL-1). The natural area lies at 43°39' N. latitude and 120°01' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area lies a short distance north of Willamette Summit on Oregon State Highway 58. There are several easy access routes into the tract. The Waldo Lake Road (Forest Road 204) bounds the northwestern corner of the natural area. The northwestern and southeastern corners of the tract can be reached by easy hikes from the end of the Gold Lake Road (Forest Road 223), via Forest

Trails 3677 or 3681, respectively. The southwestern corner of the tract can also be reached by boat travel across Gold Lake from the Gold Lake Forest Camp. Wet areas, ponds, and stream courses do make cross-country travel through the boggy portions of the natural area somewhat difficult at times.

The nearest commercial accommodations are found at Odell and Crescent Lake, along Oregon State Highway 58 east of Willamette Summit. There are numerous improved forest camps in the vicinity, including one at the outlet of Gold Lake, less than a mile from the natural area.

ENVIRONMENT

The bulk of the research natural area is located in a basin between two mountain slopes at the head of Gold Lake. The topography is essentially flat, except in the northwestern and southeastern corners, where lower mountain slopes have been incorporated within the tract. Three small ponds located within the bog are estimated to total about 1.5 ha. (4 acres). Three major streams (Ray, Salt, and Skyline Creeks) converge and flow through the tract. Elevations range from 1,463 to 1,646 m. (4,800 to 5,400 ft.).

Gold Lake Bog Research Natural Area is located in the volcanic High Cascades. Bedrock is composed of Pleocene-Pleistocene olivine basalt and basaltic andesite (Williams 1957). It is covered by aeolian deposits of volcanic ash and dacitic pumice, much of which came from the Mount Mazama eruption 6,600 years ago.

A cool, wet climate prevails. Most precipitation occurs during the winter months, and much of this accumulates in snow packs which probably attain maximum depths of 2 to 3 m. (6 to 9 ft.) on the average. Summers are relatively dry, and drought periods of 1 to 2 months are not uncommon. Climatic data from a weather station located about

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

8 km. (5 miles) southeast of the natural area at 1,459-m. (4,788-ft.) elevation (Odell Lake Land Pan in U.S. Weather Bureau 1965) are as follows:

Mean annual temperature4.8°C. (40.6°F.)
Mean January temperature-3.6°C. (25.6°F.)
Mean July temperature14.6°C. (58.3°F.)
Mean January minimum
temperature-7.5°C. (18.5°F.)
Mean July maximum temperature ..23.7°C. (74.6°F.)
Mean annual precipitation1,533 mm. (60.37 in.)
June through August
precipitation86 mm. (3.39 in.)
Average annual snowfall834 cm. (329.00 in.)

Temperatures are somewhat cooler and precipitation higher on the natural area itself; isohyetal maps indicate 1,800 to 2,000 mm. (70 to 80 in.) of precipitation are to be expected on the tract.

Soils within the natural area have not been mapped or described. In upland areas they appear to be nondescript, Brown Podzolic forest soils developed in volcanic ash. Most of the ash is probably from the eruption of Mount Mazama 6,600 years ago. Organic soil profiles are encountered in the low-lying boggy areas.

BIOTA

Approximately 75.7 ha. (187 acres) of the Gold Lake Bog Research Natural Area are occupied by bogs and marshes, 1.6 ha. (4 acres) by ponds, and 117.2 ha. (272 acres) by subalpine forest. The forested acreage can arbitrarily be divided into 58.6 ha. (136 acres) of SAF cover type 206, Engelmann Spruce - Subalpine Fir, and 58.6 ha. (136 acres) of type 205, Mountain Hemlock-Subalpine Fir (Society of American Foresters 1954). The Engelmann spruce (*Picea engelmannii*) - subalpine fir (*Abies lasiocarpa*) forests tend to occur around the periphery of the bogs and marshes, and the mountain hemlock (*Tsuga mertensiana*) - subalpine fir forests are found in upland portions of the tract. Küchler (1964) types represented would probably include Fir-Hemlock Forest (4) and Western Spruce - Fir Forest (15). The natural area is at the boundary of the *Abies amabilis* and *Tsuga mertensiana* Zones described by Franklin and Dyrness (1969).

The key features of the natural area are the bogs and marshes, but complete descriptions of these communities are not available. Most of the common bog plants occur, including sphagnum moss, *Eriophorum* spp., *Menyanthes trifoliata*, and *Kalmia polifolia*. Five species of carnivorous plants occur within the natural area: *Drosera longifolia*, *Drosera rotundifolia*, *Utricularia intermedia*, *Utricularia minor*, and *Utricularia vulgaris*. Another relatively rare plant, *Scheuchzeria palustris*, is also found in the bogs. The area is believed to incorporate several of the best examples of the sphagnum bogs found in the central Oregon Cascade Range.

The timbered area includes Engelmann spruce, subalpine fir, mountain hemlock, Pacific silver fir (*Abies amabilis*), Shasta red fir (*Abies magnifica* var. *shastensis*), lodgepole pine (*Pinus contorta*), western white pine (*Pinus monticola*), and Douglas-fir (*Pseudotsuga menziesii*) as constituent species. As mentioned, there appear to be two major forest types present. Low-lying forests bordering marshes and bogs are typically dominated by Engelmann spruce and subalpine fir. Reproduction is composed primarily of mountain hemlock and subalpine fir. Engelmann spruce attains diameters of 110 cm. (45 in.) b.h. and heights of 50 m. (160 ft.). However, many of the stands have suffered recent mortality, with windthrow being the most common agent killing the spruce and insects, the subalpine fir. Common understory species are *Viola sempervirens*, *Chimaphila umbellata*, *Pyrola secunda*, *Xerophyllum tenax*, *Clintonia uniflora*, *Rubus lasiococcus*, and *Tiarella unifoliata*.

The drier upland forests are very mixed in composition with mountain hemlock, Shasta red fir, Douglas-fir, and western white pine typically most conspicuous. The Shasta red fir and western white pine are usually largest, occasional specimens exceeding 100-cm. (40-in.) d.b.h. and 52 m. (175 ft.) in height. Mountain hemlock and Pacific silver fir often dominate the reproduction. The understory is typically sparse with species such as *Vaccinium membranaceum*, *V. scoparium*, and *Xerophyllum tenax* present.

Beaver (*Castor canadensis*) are probably the most important animals influencing natural processes within the natural area. They have developed dams and runways in some marshy areas (fig. GL-2). The natural area is used as summer range by elk (*Cervus canadensis*), blacktail deer (*Odocoileus hemionus columbianus*), and mule deer (*Odocoileus hemionus*). Badger (*Taxidea taxus neglecta*) have also been observed within the tract; their occurrence west of the summit of the Cascade Range is unusual. A complete list of mammals believed to utilize the natural area is provided in table GL-1. Birds commonly found within the natural area include blue grouse (*Dendragapus obscurus*), mountain quail (*Oreortyx pictus*), mourning doves, (*Zenaidura macroura*), band-tailed pigeons (*Columbia fasciata*), mallard ducks (*Anas platyrhynchos*), and wood ducks (*Aix sponsa*). Gold Lake is stocked with rainbow trout which have moved up into the ponds and streams within the natural area.

Several species of amphibians are known to inhabit Gold Lake Bog. The Cascade frog (*Rana cascadae*) is found near the exterior of the bog, and the western spotted frog (*Rana pretrosa*) inhabits the interior of the bog. These two closely related species are probably genetically compatible in their ability to hybridize. The northwestern tree toad (*Hyla regilla*) is also found within the area.

HISTORY OF DISTURBANCE

The major human disturbance to the natural area has been the removal of beaver dams from the main stream channel by the Oregon State Game Commission to provide access for spawning rainbow trout from Gold Lake. Since the dams appear to be of major importance in maintaining high water levels in the marshes and bogs, this practice has been discontinued since establishment of the natural area. Beaver populations have reportedly decreased considerably in the last few years, a possible consequence of trapping which is not yet prohibited on the tract. Recreationists have caused some minor disturbances; these are confined primarily to trailside areas.

Open grasslands above the bog have been used as a base camp for hunters in the late fall, however. Such use is now prohibited, and public recreational use of the bogs and marshes is discouraged.

Wildfires have undoubtedly occurred over the natural area in past centuries; however, there is no evidence of recent wildfires.

RESEARCH

Some research on plant communities² and amphibian fauna³ have been carried out within the natural area.

The natural area is, of course, particularly valuable as a site for the study of the ecology of bog and marsh communities and the fauna associated with them. It provides a refugium for the protection of six uncommon species of bog plants and a site for studying the environmental (habitat) and breeding relationships of two species of frogs. The natural area is also well suited to studies of variation in composition, structure, and productivity of forest communities along an environmental gradient extending from wet, low-lying to dry, upland areas.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Waldo Lake, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956; and *geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961), and *Geologic Map of the Central Part of the High Cascade Range, Oregon* (Williams 1957). Either the District Ranger (Oak Ridge Ranger District) or Forest Supervisor (Willamette National Forest, Eugene, Oregon) can provide details on the most recent aerial coverage and forest type maps for the area.

² Research by Dr. John Rumley, Montana State University, Bozeman.

³ Research by Dr. James Kezar, Department of Biology, University of Oregon, Eugene.

GOODLOW MOUNTAIN RESEARCH NATURAL AREA¹

A tract spanning the transition from sagebrush steppe through open ponderosa pine savanna to ponderosa pine - white fir forest characteristic of south-central Oregon.

The Goodlow Mountain Research Natural Area was established May 1942 to exemplify the transition from sagebrush (*Artemisia* spp.) steppe through open ponderosa pine (*Pinus ponderosa*) savanna to ponderosa pine - white fir (*Abies concolor*) forest along an east-west elevational gradient. The 510-ha. (1,260-acre) tract is located in Klamath County, Oregon, and is administered by the Bly Ranger District (Bly, Oregon), Fremont National Forest. Its rectangular shape is oriented east and west (fig. GM-1) encompassing part of section 4, all of section 5, and part of section 6, T. 39 S., R. 13 E., Willamette meridian, at 45°10' N. latitude and 121°15' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located about 71 km. (43 miles) east of Klamath Falls, Oregon. It is reached most readily by following State Highway 140 for 43.5 km. (27 miles) to Bonanza Junction at the foot of Bly Mountain; thence south for 3 km. (2 miles) on State Highway 70 to its junction with Forest Road 3726; thence east on Road 3726 for 11 km. (7 miles) to its junction with Forest Road 384; and south on Road 384 for 11 km.

¹ Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

(7 miles) to the natural area. Although the tract can be reached from Bly, Oregon, the road is in very poor condition and should be avoided if possible.

ENVIRONMENT

The Goodlow Mountain Research Natural Area varies in elevation from 1,490 to 1,620 m. (4,900 to 5,300 ft.). Topography is gently rolling to rolling with slopes of 10 to 20 percent. Goodlow Mountain is a low butte at the edge of the sagebrush steppe. The natural area extends from the summit of Goodlow Mountain to the forest edge. The butte is igneous rock of volcanic origin.

A continental climate prevails. Most precipitation occurs as snow during the cool, partly cloudy winter. Summers are warm, generally low in precipitation, and largely cloudless. One to 3 months of drought are common. Climatic data from Round Grove located 29 km. (18 miles) east-northeast of the natural area are as follows (U.S. Weather Bureau 1965):

Mean annual temperature6.4°C. (43.5°F.)
Mean January temperature-2.8°C. (27.0°F.)
Mean July temperature16.8°C. (62.3°F.)
Mean January minimum temperature-8.8°C. (16.1°F.)
Mean July maximum temperature27.4°C. (81.1°F.)
Average annual precipitation419 mm. (16.5 in.)
June through August precipitation56 mm. (2.2 in.)
Average annual snowfall119 cm. (47.0 in.)

Soils in the area have not been mapped. Reconnaissance notes suggest that, under forested stands, upper horizons contain aerially deposited pumice presumably from the Mount Mazama (now Crater Lake) eruption (Baldwin 1964). They tend to have minimum profile development and are not podzolized. Soils under juniper and sagebrush-grass appear to be derived from igneous rock.

BIOTA

Estimated areas by plant community are as follows:

Community	Area
<i>Pinus ponderosa</i> / <i>Purshia tridentata</i> savanna	89 ha. (220 acres)
<i>Pinus ponderosa</i> / <i>Arctostaphylos parryana</i>	218 ha. (540 acres)
<i>Pinus ponderosa</i> - <i>Abies concolor</i> / <i>Carex rossii</i>	130 ha. (320 acres)
<i>Juniperus occidentalis</i> / <i>Artemisia tridentata</i>	40 ha. (100 acres)
<i>Artemisia arbuscula</i> / <i>Poa sandbergii</i>	32 ha. (79 acres)

Pinus/Purshia and *Pinus/Arctostaphylos* stands are probably assignable to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and Küchler's (1964) Type 10, Ponderosa Pine Shrub Forest. The *Pinus-Abies/Carex* stands are possibly assignable to SAF type 214, Ponderosa Pine - Western Larch - Douglas Fir, and to Küchler's Type 14, Grand Fir-Douglas Fir Forest, even though Douglas-fir is not present in this part of Oregon. *Juniperus/Artemisia* stands are assignable to SAF type 238, Western Juniper, and Küchler's Type 24, Juniper Steppe Woodland. The *Artemisia/Poa* stands are assignable to Küchler's Type 55, Sagebrush Steppe. The natural area spans upper elevation edges of sagebrush steppe, the ponderosa pine zone, and the lower edge of the white fir zone.

At lower elevations (1,490 m. or 4,900 ft.), *Juniperus/Artemisia* stands occur. These plant communities are dominated by western juniper (*Juniperus occidentalis*), big sagebrush (*Artemisia tridentata*), and Idaho fescue (*Festuca idahoensis*). The *Artemisia/Poa* stands occur on shallow to very shallow soils and reflect these edaphic restraints. They are dominated by low sagebrush (*Artemisia arbuscula*) and Sandberg bluegrass (*Poa sandbergii*). Soil conditions are inimical to both juniper and ponderosa establishment (fig. GM-2). Where soils are deeper, Idaho fescue tends to dominate.

A small meadow complex, about 1 ha. (2

acres) in size, occurs at the eastern edge of the natural area. It is unique in that a moist meadow is located topographically above a dry meadow.

The *Pinus/Purshia* stands are characteristic of the lowest forested elevations and represent savanna transitional to sagebrush steppe. They are dominated by ponderosa pine with a crown cover of 20 to 40 percent. Ground vegetation is generally dominated by bitterbrush (*Purshia tridentata*) and Ross's sedge (*Carex rossii*) with curlleaf mountain-mahogany (*Cercocarpus ledifolius*) and a variety of Compositae spp. as associates (fig. GM-2). Midelevations are characterized by ponderosa pine of 30- to 50-percent crown cover with Parry manzanita (*Arctostaphylos parryana*) and occasional bitterbrush with sedge (fig. GM-2). Upper elevations are characterized by old-growth ponderosa pine with seedlings, saplings, and poles, and occasionally mature trees of white fir. Tree crown cover ranges from 40 to 70 percent. Ground vegetation is dominated by Ross's sedge with minor amounts of Parry manzanita (fig. GM-2).

Mammals which frequent the natural area either as residents or transients are listed in table GM-1.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine (fig. GM-2) indicate ground fires periodically burned the area prior to initiation of fire control programs in 1910. Ranger District records document a ground fire between 1920 and 1930. In addition, a severe fire in 1918 (known as the Goodlow Mountain Burn) burned over 16 ha. (41 acres) of the southwestern corner of the natural area and killed 100 percent of the timber. A very dense stand of pine reproduction is now present in this area.

Prior to establishment of the natural area, an 800-ewe band of sheep grazed the tract periodically from the middle of June to the end of August. Ranger District records indicate this livestock use was light to moderate and should not have materially affected vegetation. Sheep use is now terminated.

RESEARCH

The Bureau of Entomology and Plant Quarantine has been studying bark beetle activity in section 5 since 1922. Between 1938 and 1940, two 10-acre plots were established in which all trees of 10-inch and larger d.b.h. were tagged, recorded, and fully described. These permanent plots are still under observation.

The Goodlow Mountain Research Natural Area provides interesting research opportunities on: (1) comparison of undisturbed vegetation across the geographic range of the aerially deposited Mount Mazama pumice in conjunction with Bluejay and Pringle Falls Research Natural Areas in the center and at the northern edge of the pumice deposit, respectively; (2) evaluation of environmental and plant community relationships from sagebrush steppe to mixed coniferous forest; (3) biomass productivity in relation to the environmental gradient; and (4) study of forest succession under fire prevention.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are

sufficiently detailed to be useful. Either the District Ranger (Bly Ranger District) or Forest Supervisor (Fremont National Forest, Lakeview, Oregon) can provide details on the most recent aerial photo coverage of the area.

HADES CREEK RESEARCH NATURAL AREA¹

Pacific silver fir-western hemlock stands located at low elevations on the northwestern edge of the Olympic Peninsula.

The Hades Creek Research Natural Area was established to exemplify Pacific silver fir (*Abies amabilis*) - western hemlock (*Tsuga heterophylla*) forest as it occurs at lower elevations in the Olympic Mountains. The 227-ha. (560-acre) tract is located in Jefferson County, Washington, and is administered by Olympic National Park (Port Angeles, Washington). The natural area occupies the S1/2 and S1/2 NW1/4 of section 5 and N1/2 N1/2 of section 8, T. 27 N., R. 11 W., Willamette meridian. It lies at 47°52' N. latitude and 124°09' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is reached via the Bogachiel River Road (which leaves U.S. Highway 101 about 10 km. or 6 miles south of Forks) and the Bogachiel River Trail. The tract is located about 10 km. (6 miles) from the end of the road near the Bogachiel Shelter; it is necessary to ford the river about 1/4 mile above the shelter since it is on the north side of the river and the natural area is on the south. The natural area is located on slopes west of Hades Creek (fig. HA-1). An abandoned trail extends from the river to the sum-

mit of Spruce Mountain and traverses a large part of the natural area.

Commercial accommodations are, of course, quite remote, the nearest being located in the vicinity of Forks, which is several hours away by trail and road. There are numerous good camp spots along the Bogachiel River in the vicinity of the natural area. When camping in undeveloped areas, one must obtain a fire permit from the Park Service.

ENVIRONMENT

Hades Creek Research Natural Area occupies the top and slopes of a spur ridge on the lower slopes of Spruce Mountain and extends down to the benches along the Bogachiel River. Moderately steep slopes are typical except along the southern edge of the natural area, where the topography drops steeply into the drainage of Hades Creek. The gentlest slopes are found on the benches just above the Bogachiel River. Elevations in the natural area range from about 145 to 582 m. (475 to 1,910 ft.).

The natural area is located on upper Cretaceous - lower Tertiary sedimentary rocks belonging to the Soleduck formation (Hunting et al. 1961). This formation developed from marine sediments which were intensely folded and faulted and slightly metamorphosed (Danner 1955). The dominant, dark gray, massive to poorly bedded graywackes and sandstones are commonly interbedded with slate, argillite, and volcanic rock. The natural area was glaciated at least three times during the Wisconsin epoch and at least once even earlier (Crandell 1964).

A maritime climate, wet with muted temperature extremes, prevails. Winters are mild, and summers are cool with frequent cloudy days. Precipitation is heavy but highly seasonal, with January and December the peak months. Less than 10 percent of the annual

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

precipitation falls during June, July, and August, and some years a drought period of a month or more occurs. The following climatic data are from Forks, located about 19 km. (12 miles) to the northwest; temperatures are somewhat cooler and precipitation slightly higher on the natural area itself (U.S. Weather Bureau 1965):

Mean annual temperature9.55°C. (49.2°F.)
Mean January temperature3.72°C. (38.7°F.)
Mean July temperature15.39°C. (59.7°F.)
Mean January minimum
temperature0.17°C. (32.3°F.)
Mean July maximum temperature ..21.55°C. (70.8°F.)
Average annual precipitation ..2,974 mm. (117.10 in.)
June through August
precipitation214 mm. (8.44 in.)
Average annual snowfall34 cm. (13.7 in.)

The soils on the area have not been mapped or described. At least a portion would probably be classed as Sols Bruns Acides.

BIOTA

All 227 ha. (560 acres) of the natural area can be classified as SAF cover type 226, Pacific Silver Fir - Western Hemlock (Society of American Foresters 1954). The area would probably fall within Küchler's (1964) Type 3, Silver Fir - Douglas-fir Forest, and the *Tsuga heterophylla* Zone as defined by Franklin and Dyrness (1969). A zonal assignment is difficult for this area since it is occupied by forests which are more typically found at much higher elevations.

Pacific silver fir and western hemlock dominate the Hades Creek Research Natural Area. The relative proportion of the tree species varies considerably throughout the tract. For example, silver fir composes about 80 percent of the stand volume on the ridge-top but only 20 percent near Hades Creek on the south side of the area and on the north end. The bulk of the area varies from about a 60-40 to a 50-50 mixture of Pacific silver fir and western hemlock, respectively. Pacific silver fir within the natural area averages 75- to 90-cm. (30- to 35-in.) d.b.h. and 46 to 53 m. (150 to 175 ft.) in height. The largest known Pacific silver fir specimen, which is 56.7 m. (186 ft.) in height and about 208- cm.

(82-in.) d.b.h. is located within the natural area (Pomeroy and Dixon 1966) (fig. HA-2). Occasional large, old-growth Douglas-fir (*Pseudotsuga menziesii*) and western red-cedar (*Thuja plicata*) are also found throughout the natural area.

The major climax tree species within the natural area appears to be western hemlock. Seedlings and saplings of this species are typically much more common than those of Pacific silver fir, especially on drier sites. This is, of course, in direct contrast with the successional relationship between these species at middle and high elevations in the Olympic and Cascade Mountains (Fonda and Bliss 1969, Franklin and Dyrness 1969). Pacific silver fir is probably at least a minor climax species, as at least some reproduction of this species is present in most locations.

At least two major community types occur within the natural area: the *Tsuga heterophylla* - *Abies amabilis*/*Gaultheria shallon* - *Vaccinium parvifolium*/*Hylocomium splendens* and *Abies amabilis*/*Tsuga heterophylla*/*Maianthemum bifolium* communities. The *Tsuga*/*Gaultheria*/*Hylocomium* community is typical of lower elevations and drier slopes within the natural area. Understory plant species include: *Gaultheria shallon*, *Viola sempervirens*, *Acer circinatum*, *Blechnum spicant*, *Vaccinium parvifolium*, and *Eurhynchium oreganum*. The *Abies*/*Tsuga*/*Maianthemum* community appears to be typical of moister habitats within the natural area. The understory is dominated by herbaceous species such as *Maianthemum bifolium* var. *kamschaticum*, *Rubus pedatus*, *Oxalis oregana*, *Polystichum munitum*, *Disporum* sp., *Blechnum spicant*, *Tiarella trifoliata*, and *Trillium ovatum*.

Mammals believed to utilize the natural area either as residents or transients are listed in table HA-1.

Streams and streamsides are the only specialized habitats known to occur within the natural area.

HISTORY OF DISTURBANCE

There is no evidence of any unusual natural disturbance of the area during recent cen-

turies. Natural mortality such as that caused by windthrow is scattered throughout the tract.

Human disturbances to the natural area are very minor. An abandoned trail was constructed and used during World War II to supply an air-warning station on Spruce Mountain.

RESEARCH

Ten Pacific silver fir "trend plots" were established on the natural area in 1954 to observe annual mortality of Pacific silver fir and western hemlock, particularly that associated with the silver fir beetle (*Pseudohylesinus* spp.).² At the time of the first remeasurement in 1958, mortality of Pacific silver fir had been negligible (Buckhorn and Orr 1959).

The natural area provides interesting oppor-

² "Silver fir beetles" is a local name given to two species of *Pseudohylesinus*: *P. grandis*, the grand fir bark beetle, and *P. granulatus*, the fir root bark beetle.

tunities to study the ecology of low-elevation Pacific silver fir - western hemlock stands, e.g., the successional relationships between these tree species including variations associated with different types of microhabitats.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Spruce Mountain, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956, and Olympic National Park and Vicinity, Washington, scale 1:125,000, issued by the U.S. Geological Survey in 1957; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Huntting et al. 1961). The Superintendent, Olympic National Park (Port Angeles, Washington), can provide details on the most recent aerial photo coverage and forest type maps for the area.

HIGLEY CREEK RESEARCH NATURAL AREA¹

Western hemlock stands on a mountain slope and valley bottom on the southwestern Olympic Peninsula.

The Higley Creek Research Natural Area was established to exemplify coastal western hemlock (*Tsuga heterophylla*) forest stands. The 194-ha. (480-acre) tract is located in Grays Harbor County, Washington, and is administered by the Olympic National Park (Port Angeles, Washington). The natural area occupies the S1/2 and the S1/2 N1/2, section 12, T. 23 N., R. 10 W., Willamette meridian. It lies at 47°30' N. latitude and 123°54' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located near Lake Quinault and can be reached via U.S. Highway 101 (to Amanda Park) and the North Shore Road along the lake. The edge of the tract varies from 750 to 1,200 m. (2,500 to 4,000 ft.) north of this road. An abandoned trail leads up Higley Creek from this road skirting the natural area; its obscure terminus is located behind a house 2.7 km. (1.7 miles) from U.S. Highway 101 or 6.9 km. (4.3 miles) west of the National Park Service's Quinault Ranger Station. No roads or maintained trails enter the tract. Access is by cross-country travel.

Commercial accommodations, as well as several excellent public campgrounds, are located 3 to 8 km. (2 to 5 miles) from the

natural area in the vicinity of Amanda Park and Quinault.

ENVIRONMENT

The Higley Creek Research Natural Area extends from the floor of the Quinault River valley onto the lower slopes of Higley Peak (fig. HI-1). Topography is gentle and undulating for 300 to 800 m. (1,000 to 2,500 ft.) from the southern boundary of the tract and then rises steeply to the northern boundary. The broken mountain slopes typically vary from 30 to 50 percent and have a generally southern exposure. Several streams flow through portions of the natural area, and several smaller streams rise within it. Drainages cut by these streams produce locally complex microtopography in the southern half of the tract. Elevations range from about 120 m. (400 ft.) in the southwestern corner to 550 m. (1,800 ft.) in the northwestern corner.

According to Hunting et al. (1961), higher elevations in the natural area are located on upper Cretaceous-lower Tertiary sedimentary rocks belonging to the Soleduck formation, while at lower elevations these rocks are covered by recent deposits of alluvium and, possibly, glacial drift. The Soleduck formation developed from marine sediments which have been intensely folded and faulted and slightly metamorphosed (Danner 1955). The dominant, dark gray, massive to poorly-bedded graywackes and sandstones are commonly interbedded with slate, argillite, and volcanic rock. The natural area was glaciated at least three times during the Wisconsin epoch and at least once before that (Crandell 1964).

A maritime climate, wet with muted temperature extremes, prevails. Winters are mild and summers are cool with frequent cloudy days. Precipitation is heavy but highly seasonal with January and December the peak months. Only about 7 percent of the annual

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

precipitation falls during June, July, and August; and some years a drought period of a month or more occurs. Snow is rare. Climatic data from the nearby Quinault Ranger Station are as follows (U.S. Weather Bureau 1956):

Mean annual temperature10.6°C. (51.0°F.)
Mean January temperature3.8°C. (38.9°F.)
Mean July temperature17.3°C. (63.2°F.)
Mean January minimum temperature1.2°C. (34.2°F.)
Mean July maximum temperature	..23.8°C. (74.9°F.)
Average annual precipitation	..3,371 mm. (132.73 in.)
June through August precipitation244 mm. (9.61 in.)
Average annual snowfall30.2 cm. (11.9 in.)

The soils on the area have not been mapped or described. In the valley bottom, they appear relatively deep and loamy, and on the mountain slopes they are somewhat shallower and contain greater amounts of loose rock. At least a portion of the soils would probably be classed as Sols Bruns Acides.

BIOTA

Essentially all 194 ha. (480 acres) of the natural area are occupied by SAF cover type 224, Western Hemlock (Society of American Foresters 1954). The area would probably fall entirely within Küchler's (1964) Type 1, Spruce - Cedar - Hemlock Forest, and contains elements of both the *Picea sitchensis* and *Tsuga heterophylla* Zones as defined by Franklin and Dyrness (1969).

Western hemlock is the most abundant tree within the research natural area, attaining diameters of 75 to 100 cm. (30 to 40 in.) b.h. and heights of 60 m. (200 ft.). Specimens up to 152-cm. (60-in.) d.b.h. and larger are occasionally encountered (fig. HI-2). Other coniferous tree species include western redcedar (*Thuja plicata*), Douglas-fir (*Pseudotsuga menziesii*), Pacific silver fir (*Abies amabilis*), and Sitka spruce (*Picea sitchensis*). Western redcedar is most common in wet areas on gentle topography, where it may occur as very large (in excess of 254-cm. or 100-in. d.b.h.), old specimens. Douglas-fir is common as large, old trees, averaging 125- to 150-cm. (50- to 60-in.) d.b.h. with a maximum

of about 203 cm. (80 in.). Both Pacific silver fir and Sitka spruce are rare, the former being encountered on the mountain slopes and the latter on the flat topography in the valley bottom. Red alder (*Alnus rubra*) is common along larger streams and in some swampy areas (fig. HI-2). Bigleaf maple (*Acer macrophyllum*) is also occasionally found on moist slopes or along streambanks.

Western hemlock is clearly the climax species throughout most of the natural area; it is the only species consistently represented by all age classes. Seedlings and saplings of hemlock are abundant; some stand openings are completely choked by sapling hemlocks. Reproduction of western redcedar, Douglas-fir, and Sitka spruce is generally absent. Much tree reproduction is found on rotting logs, "nurse logs," which often support hundreds of seedlings. Some of these can be expected to survive and their roots to reach mineral soil.

Four major community types were recognized within the natural area during the reconnaissance. These were (1) *Tsuga heterophylla*/*Polystichum munitum* - *Oxalis oregana*; (2) *Thuja plicata* - *Tsuga heterophylla*/*Vaccinium alaskaense* - *Gaultheria shallon*/*Blechnum spicant*; (3) *Tsuga heterophylla* - *Pseudotsuga menziesii*/*Gaultheria shallon* - *Vaccinium parvifolium*; and (4) an *Alnus rubra* swamp type. The most common community type is the *Tsuga*/*Polystichum* - *Oxalis* which is found both on mountain slopes and in the valley bottom. Typical understory species in this community include *Polystichum munitum*, *Oxalis oregana*, *Blechnum spicant*, *Tiarella trifoliata*, *Maianthemum bifolium* var. *kamschaticum*, *Galium triflorum*, and *Viola sempervirens*. The shrubby layer is not well developed, consisting primarily of *Vaccinium parvifolium*.

The *Thuja* - *Tsuga*/*Vaccinium* - *Gaultheria*/*Blechnum* community is found on relatively wet habitats and gentle topography. The shrubby layer in this community is dominated by *Vaccinium alaskaense* and *Gaultheria shallon*. Important herbs include *Blechnum spicant*, *Rubus pedatus*, *Cornus canadensis*, *Polystichum munitum*, *Gymnocarpium dryop-*

teris, *Athyrium filix-femina*, *Tiarella trifoliata*, and *Galium triflorum*.

The *Tsuga* - *Pseudotsuga*/*Gaultheria* - *Vaccinium* community is generally found on drier habitats on the slopes. Vine maple (*Acer circinatum*) is a common shrub dominant along with the *Gaultheria shallon*. Other shrubby species include *Berberis nervosa*, *Vaccinium parvifolium*, and *Rubus ursinus*. Herbaceous species may include *Polystichum munitum*, *Oxalis oregana*, *Trillium ovatum*, and *Viola sempervirens*.

Extremely wet or swampy areas on gentle topography are occupied by an open mosaic of tree, shrub, and herb-dominated stands (fig. HI-2). Red alder is the conspicuous tree species in such areas. These mosaics provide a rich variety of microhabitats for many plant and animal species not found elsewhere in the natural area. Plant dominants include the shrubs vine maple, *Gaultheria shallon*, *Rubus spectabilis*, *Menziesia ferruginea*, *Corydalis scouleriana*, *Stachys* sp., *Rhamnus purshiana*, and *Sambucus* sp. The rich selection of herbs includes *Athyrium filix-femina*, *Lysichitum americanum*, *Gymnocarpium dryopteris*, *Carex* spp., *Scirpus* sp., *Boykinia major*, *Cardamine* sp., and *Chrysosplenium glechomae-folium*, as well as several species of grass.

The Roosevelt elk (*Cervis canadensis roosevelti*) is the most important animal present on the natural area; their trails ease the problem of access through the area. Undoubtedly they have also affected the composition of the understory vegetation (Kirk 1966, Sharpe 1956). Mammals believed to occur within the natural area are listed in table HI-1.

Streams and streamside are the only specialized habitats which are present. No lakes, ponds, rock outcrops, etc., exist within the natural area.

HISTORY OF DISTURBANCE

The most common natural disturbance encountered within the natural area is windthrow of trees, which may occur either singly or in small patches (fig. HI-2). There is no evidence of recent wildfires; fire scars can be seen on very old Douglas-firs. The parasitic dwarf mistletoe (*Arceuthobium campylopodum*) is commonly found on western hemlock within the natural area. Human disturbance within the natural area is essentially nonexistent.

RESEARCH

No research is presently known to be in progress within the natural area. Special research opportunities existing here include studies of contrasts in community composition and structure associated with variations in soils and topography, and effects of Roosevelt elk on their habitat.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Quinault Lake, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955, and topographic map of Olympic National Park and Vicinity, Washington, scale 1:125,000, issued by the U.S. Geological Survey in 1957; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). The Superintendent, Olympic National Park (Port Angeles, Washington), can provide details on the most recent aerial photo coverage and forest type maps for the area.

HORSE RIDGE RESEARCH NATURAL AREA¹

A unique western juniper/big sagebrush/threadleaf sedge community in near pristine condition.

The Horse Ridge Research Natural Area was established March 1967 as an example of western juniper (*Juniperus occidentalis*) - big sagebrush (*Artemisia tridentata*) vegetation within the juniper zone of central Oregon. The 240-ha. (600-acre) tract is located in Deschutes County, Oregon, and is administered by the Prineville District (Prineville, Oregon), Bureau of Land Management. The rectangular tract is located in sections 15 and 22, T. 19 S., R. 14 E., Willamette meridian, at 43°55' N. latitude, 120°02' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located about 31 km. (19 miles) southeast of Bend and is approached via U.S. Highway 20. Directions for locating the tract should be obtained at the Prineville District Office. Access is good during both summer and winter. Public accommodations are available in Bend; primitive camps which lack drinking water are available in the vicinity of the tract.

ENVIRONMENT

The Horse Ridge Research Natural Area varies in elevation from 1,250 to 1,430 m. (4,100 to 4,700 ft.). It is located on top of rolling topography (Horse Ridge) which rises

above the surrounding flat to undulating plateau (fig. HR-2). Columbia River basalts underlie the entire area.

A continental climate prevails. Most precipitation occurs as snow during the cool, partly cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 4 months of drought are common. Climatic data from Bend are as follows (U.S. Weather Bureau 1965):

Mean annual temperature7.9°C. (46.3°F.)
Mean January temperature-1.0°C. (30.2°F.)
Mean July temperature17.6°C. (63.7°F.)
Mean January minimum temperature-6.5°C. (20.3°F.)
Mean July maximum temperature	..28.6°C. (83.6°F.)
Average annual precipitation305 mm. (12.0 in.)
June through August precipitation56 mm. (2.2 in.)
Average annual snowfall91 cm. (36.0 in.)

Soils in the area have not been mapped. cursory examination suggests they are sandy textured and developed in 30 to 60 cm. (12 to 24 in.) of aerially deposited pumice over well cracked basalt bedrock.

BIOTA

Nearly all of the 240 ha. (600 acres) is characterized by a western juniper/big sagebrush/threadleaf sedge (*Carex filifolia*) community. A small area at the eastern edge is occupied by a stand of western juniper/big sagebrush/bluebunch wheatgrass (*Agropyron spicatum*) with abundant surface stone. Vegetation can probably be assigned to SAF forest cover type 238, Western Juniper (Society of American Foresters 1954), and Küchler's (1964) Type 24, Juniper Steppe Woodland. The area falls within the *Juniperus occidentalis* Zone of central Oregon (Franklin and Dyrness 1969).

The major plant community (fig. HR-2) is dominated by western juniper which conspicuously lacks decadent or dead specimens.

¹ Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

Ground vegetation is dominated by big sagebrush and threadleaf sedge with some dead and decadent bitterbrush (*Purshia tridentata*), bluebunch wheatgrass, Idaho fescue (*Festuca idahoensis*), *Koeleria cristata*, and *Tetradymia canescens*. The soil surface is characteristically bare of litter and is covered by fine pumice gravel, 2- to 5-mm. diameter.

This plant community is interesting in several ways. Hybridization of bluebunch wheatgrass and bottlebrush squirreltail (*Sitanion hystrix*) appears to be more common on this tract than elsewhere in the central Oregon juniper zone. Western juniper appears to affect distribution of plant species (fig. HR-2) — within the crown and root zone of western juniper, Idaho fescue tends to assume clear dominance to the near exclusion of big sagebrush and great reduction in threadleaf sedge. These conditions and the general dominance of threadleaf sedge tend to make this vegetation unique in the central Oregon area. Driscoll (1964) did not find this plant community common enough to warrant classification in his study of plant communities in central Oregon western juniper. Furthermore, this area apparently represents essentially ungrazed conditions; forage utilization data gathered by the Prineville District suggest that threadleaf sedge is sensitive to grazing and quickly decreases in abundance under heavy livestock use.

A list of mammals believed to utilize the natural area is provided in table HR-1. Mule deer (*Odocoileus hemionus*) are occasionally year around residents but frequently use the area for winter range.

HISTORY OF DISTURBANCE

An occasional burned-out juniper of large diameter can be found on the tract, indicating fires have occurred. Evidence of the extent of these fires could not be found. Normally only single trees are struck by lightning and burn, fires rarely spreading because of insufficient ground fuels.

Domestic livestock have apparently had little impact on the Horse Ridge Research

Natural Area. Permanent water is a considerable distance below the ridge, suggesting that livestock have never been attracted to the area. As mentioned earlier, records in the Prineville District Office suggest livestock overuse causes a reduction in threadleaf sedge; the abundance of the sedge suggests minimal livestock disturbance. However, fencing may be necessary to prevent stock and increasing numbers of people from using the area.

RESEARCH

Baseline population levels of several bird and mammal species are presently under study on Horse Ridge Research Natural Area.² This is part of a larger, long-term eastern Oregon study which utilizes several other research natural areas in contrasting vegetation types. Research to date involves estimation of breeding bird populations based upon weekly, early-morning censuses during the breeding season within a 20-ha. (50-acre) grid and along a line transect.

The natural area provides interesting opportunities for research on: (1) hybridization of bluebunch wheatgrass with squirreltail and possibly native ryegrass (*Elymus* spp.); (2) evaluation of this unique plant community and the place of threadleaf sedge within the western juniper zone of central Oregon; and (3) evaluation of microchanges in herbaceous dominance as apparently influenced by juniper.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are sufficiently detailed to be useful. The District Manager (Prineville District, Bureau of Land Management) can provide details on the most recent aerial photo coverage of the area.

² Research by Jay S. Gashwiler, Bureau of Sport Fisheries and Wildlife, Silviculture Laboratory, Bend, Oregon.

JACKSON CREEK RESEARCH NATURAL AREA¹

**An old-growth Douglas-fir stand
growing on a major river terrace
in the western Olympic Peninsula.**

The Jackson Creek Research Natural Area was established to exemplify the Douglas-fir (*Pseudotsuga menziesii*) forest type as it occurs on the western Olympic Peninsula. The 65-ha. (160-acre) tract is located in Jefferson County, Washington, and is administered by the Olympic National Park (Port Angeles, Washington). The natural area is rectangular occupying the NE¼ NE¼ section 13, T. 27 N., R. 10 W., and N½ NW¼ and NW¼ NE¼ section 18, T. 27 N., R. 9 W., Willamette meridian (fig. JC-1). It lies at 47°51' N. latitude and 123° 55' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located on the south bank of the Hoh River immediately opposite the Hoh River Ranger Station and campground. The ranger station is at the end of the Hoh River Road about 30 km. (19 miles) from U.S. Highway 101. To reach the natural area, it is necessary to ford the Hoh River. This generally requires scouting up river from the campground until a log jam suitable for crossing is located. During recent years, such a log jam has been located only a short distance above the central campground area,

but conditions change periodically. Although there are no trails, cross-country travel within the natural area is not difficult because of the open nature of the forest stand.

Commercial accommodations are available in Forks or Kalaloch, along U.S. Highway 101, from 48 to 64 km. (30 to 40 miles) away. However, the public campground at the end of the Hoh River Road is excellent, and there are several smaller state campgrounds along the road outside of the Park.

ENVIRONMENT

The natural area occupies gentle topography on terraces and benches in the Hoh River valley. Elevations range from about 207 to 402 m. (680 to 1,320 ft.). Jackson Creek flows through the middle of the natural area. The natural area is located on upper Cretaceous-lower Tertiary sedimentary rocks belonging to the Soleduck formation (Danner 1955, Huntington et al. 1961). However, bedrock is buried entirely beneath depositions of alluvium and, possibly, glacial drift at higher elevations. The valley of the Hoh River, including the natural area, was glaciated at least three times during the Wisconsin epoch and at least once before that (Crandell 1964).

A wet, mild, maritime climate prevails. Winters are mild, and summers are cool with frequent cloudy days. Precipitation is heavy, but less than 10 percent falls during summer months. The following climatic data are from the Forks Weather Station located approximately 35 km. (22 miles) northwest of the natural area (U.S. Weather Bureau 1965):

Mean annual temperature	9.55°C. (49.2°F.)
Mean January temperature	3.72°C. (38.7°F.)
Mean July temperature	15.39°C. (59.7°F.)
Mean January minimum temperature	0.17°C. (32.3°F.)
Mean July maximum temperature	21.55°C. (70.8°F.)

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

Average annual precipitation . . . 2,974 mm. (117.10 in.)
June through August

precipitation 214 mm. (8.44 in.)

Average annual snowfall 348 cm. (13.70 in.)

Precipitation is significantly higher on the natural area itself, probably averaging about 3,600 mm. (142 in.) annually (Kirk 1966).

Soils appear to be predominantly Sols Bruns Acides. Fonda² has described profiles with A1-B1-B2-C sequences from terraces in the vicinity of the natural area. The A1 horizons are apparently relatively thick (0 to 16 cm.).

BIOTA

Essentially all 65 ha. (160 acres) of the natural area can be classified as SAF forest cover type 229, Pacific Douglas-Fir (Society of American Foresters 1954). It would probably fall entirely within Küchler's (1961) Type 1, Spruce-Cedar-Hemlock Forest, and the *Picea sitchensis* Zone as defined by Franklin and Dyrness (1969).

Four coniferous tree species are known to occur within the Jackson Creek Research Natural Area: Douglas-fir, western hemlock (*Tsuga heterophylla*), Sitka spruce (*Picea sitchensis*), and western redcedar (*Thuja plicata*). Douglas-fir is overwhelmingly dominant, surprisingly so for a stand estimated to be around 275 years in age. Samples within the natural area indicate about 72 sq. m. per hectare of basal area (314 sq. ft. per acre), of which 87 percent is Douglas-fir.³ Trees average 125- to 150-cm. (50- to 60-in.) d.b.h. and 68 m. (225 ft.) in height with maximum diameters of about 235 cm. (94 in.) b.h. (fig. JC-2). Western hemlock is well distributed over the natural area, but averages only about 11 percent of the stand volume. Western hemlock has relatively little representation in intermediate size classes (saplings and poles). Sitka spruce is generally uncommon in the overstory but is commonly encountered as reproduction growing on down logs; it is most common in swampy areas

found in some portions of the natural area. Occasional red alder (*Alnus rubra*) and big-leaf maple (*Acer macrophyllum*) may also be encountered in the wetter, open areas.

The major climax species on the natural area appears to be western hemlock, although age class distributions indicate the climax condition is still far in the future. Sitka spruce may also be a minor climax species in these forests, since reproductive size classes up to saplings and small poles are encountered through most of the area. Climax status for the Sitka spruce would apparently contrast with normal conditions for the *Picea sitchensis* Zone (Franklin and Dyrness 1969). This is probably a partial consequence of the special conditions found in so-called "rain forest" valleys of the western Olympic Peninsula, e.g., the relatively open nature of many of the stands and selective grazing of hemlock seedlings by elk.⁴

Several community types can be recognized within the natural area including: (1) *Pseudotsuga menziesii*/*Pteridium aquilinum*-*Achlys triphylla*, (2) *Pseudotsuga menziesii*/*Polystichum munitum*-*Oxalis oregana*, (3) *Picea sitchensis*/*Acer circinatum*/*Pteridium aquilinum*. The *Pseudotsuga*/*Pteridium*-*Achlys* community occupies much of the actual river-terrace habitat within the natural area (fig. JC-2). Typical species include *Pteridium aquilinum*, *Oxalis oregana*, *Tiarella trifoliata*, *Vaccinium parvifolium*, *Achlys triphylla*, *Rubus pedatus*, *Blechnum spicant*, *Luzula parviflora*, *Trisetum cernuum*, *Carex deweyana*, and *Maianthemum bifolium* var. *kamschaticum*. The *Pseudotsuga*/*Polystichum*-*Oxalis* community is very similar in composition, lacking only the dominance of *Pteridium aquilinum*. This community type is most common in the eastern half of the natural area on gentle slopes and a higher level bench. The *Picea*/*Acer*/*Pteridium* community typifies the very open areas which appear relatively swampy in character. Tree cover is very low in these openings, but the coverage of brush species such as vine maple (*Acer circinatum*) and herbs such as *Pteri-*

² Personal communication from Dr. Richard W. Fonda, Biology Department, Western Washington State College, Bellingham.

³ See footnote 2.

⁴ See footnote 2.

dium aquilinum and various grasses and sedges is quite high.

The most important mammal within the natural area is the Roosevelt elk (*Cervus canadensis roosevelti*) which is particularly common during the winter and spring. A list of mammals believed to utilize the tract is provided in table JC-1.

Jackson Creek, which flows through the natural area for a small portion of its length, provides the only aquatic habitat within the natural area. The open swampy areas undoubtedly provide additional specialized habitat for a variety of plant and animal species not typical of the heavily forested area.

HISTORY OF DISTURBANCE

The Douglas-fir stand present on the natural area probably originated with a wildfire approximately three centuries ago; however, no fire scars were seen, which would provide evidence for more recent wildfires.

Human disturbance of the area appears to be very minor despite its proximity to the Hoh River campground; the Hoh River undoubtedly provides a major barrier against casual use of the area.

RESEARCH

The only research work known to have been conducted within the natural area is an

examination and description of the Douglas-fir stands in connection with a study of the relationship between forest communities and environmental conditions in the Hoh River valley.⁵ The natural area would appear to offer unusually good opportunities for studies of: (1) successional development and the factors which have retarded the rate of natural succession from Douglas-fir to hemlock; (2) the effect of Roosevelt elk on community composition and forest succession; and (3) occurrence of animals in sharply contrasting but contiguous community types (dense Douglas-fir forest vs. wet, brush- and herb-dominated openings).

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography*—15' Mount Tom, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955, and Olympic National Park and Vicinity, Washington, scale 1:125,000, issued by the U.S. Geological Survey in 1957; and *geology*—*Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). The Superintendent, Olympic National Park (Port Angeles, Washington), can provide details on the most recent aerial photo coverage and forest type maps for the area.

LAKE TWENTYTWO RESEARCH NATURAL AREA¹

“Subalpine” lake and old-growth western redcedar - western hemlock forest on a rugged mountain slope in the northern Cascades of Washington.

The Lake Twentytwo Research Natural Area was established on January 14, 1947, as a sample of virgin old-growth western redcedar (*Thuja plicata*) - western hemlock (*Tsuga heterophylla*) forest. The 320-ha. (790-acre) tract is located in Snohomish County, Washington, and is administered by the Monte Cristo Ranger District (Granite Falls, Washington), Mount Baker National Forest. It includes: section 22 (except NW1/4 and W1/2 SW1/4), W1/2 SW1/4, SW1/4 NW1/4, and S1/2 NW1/4 NW1/4 of section 23; and NE1/4 and E1/2 NW1/4 of section 27, T. 30 N., R. 8 E., Willamette meridian (fig. LA-1). It lies at 48°04' N. latitude and 121°46' W. longitude.

ACCESS AND ACCOMMODATIONS

Access to the vicinity is via U.S. Highway 2 and State Highways 9 and 92 from Everett to Granite Falls and Forest Highway 7 to Verlot Ranger Station. Beyond the ranger station, follow Forest Highway 7 for 2.9 km. (1.8 miles) to the start of the Lake Twentytwo Trail.

The Lake Twentytwo Trail lies almost entirely within the natural area and traverses

a large part of it. The trail climbs for 4 km. (2.5 miles) and 425 m. (1,400 ft.) of elevation to its terminus at the lake. There are no other trails or roads within the natural area boundary, and cross-country access to that part of the tract east of Twentytwo Creek and Twentytwo Lake is difficult.

The nearest commercial overnight accommodations are in Everett about 40 km. (25 miles) away, although food can be obtained at Verlot and Granite Falls. There are seven public campgrounds with 3 to 8 km. (2 to 5 miles) of the natural area.

ENVIRONMENT

The Lake Twentytwo Research Natural Area occupies essentially the entire drainage of Lake Twentytwo Creek except for some of the rugged cliffs and rock ridges south and west of Lake Twentytwo. Elevations range from about 335 m. (1,100 ft.) above sea level near the South Fork of the Stillaguamish River to about 1,100 m. (3,600 ft.) on the ridges southeast and west of Lake Twentytwo. Topography is steep to very steep and broken; a few small benches are present.

Lake Twentytwo lies entirely within the natural area. It is a 17.9-ha. (44.1-acre) lake with a maximum measured depth of 16 m. (53 ft.) (Wolcott 1961). The lake was created by glacial activity. Despite its location at a relatively low elevation of 750 m. (2,460 ft.), the lake and its environs have many aspects of a much higher subalpine lake; permanent snowfields are found within the lake basin (fig. LA-2).

The natural area is located on two major geologic formations (Huntting et al. 1961). Rocks in the upper part of the natural area are granitic intrusive rocks of Tertiary - Cretaceous age, while those at lower elevation are upper Jurassic - lower Cretaceous sedimentary rocks. The cirque basin in which Lake

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

Twentytwo is located, as well as the lake itself, are obviously glacial features which originated during the Pleistocene.

The natural area is subject to a wet, cool, maritime climate. Annual precipitation is heavy and highly seasonal, although rain is not uncommon during the summer months. Summers are cool. This regional cool, wet climate is, of course, accentuated on the steep north slope occupied by the natural area. Climatic data from the nearest weather bureau station — Darrington, Washington, about 24 km. (15 miles) northeast — are as follows (U.S. Weather Bureau 1956, 1965). They probably approximate climatic conditions encountered at lower elevations in Lake Twentytwo Research Natural Area:

Mean annual temperature9.6°C. (49.4°F.)
Mean January temperature1.1°C. (33.9°F.)
Mean July temperature17.4°C. (63.3°F.)
Mean January minimum temperature-3.2°C. (26.1°F.)
Mean July maximum temperature25.9°C. (78.7°F.)
Average annual precipitation	...2,045 mm. (80.51 in.)
June through August precipitation155 mm. (6.06 in.)
Average annual snowfall120 cm. (47.4 in.)

Soils on the natural area have recently been mapped by U.S. Forest Service personnel as part of a soil survey of the Mount Baker National Forest (Snyder and Wade 1970). Most of the higher elevational area surrounding Lake Twentytwo is shown on the map as talus slopes and intrusive igneous rock outcrop areas. In the eastern, midelevation portion of the area soils are derived from meta-sedimentary rocks and are classed as coarse loamy, mixed Typic Ferroids. These soils have a dark reddish brown loam surface layer which is underlain at about 55 cm. (22 in.) by dark yellowish brown very gravelly loam. The more gently sloping low elevational areas near the northern boundary are occupied by three soil units derived from glacial drift material. These soils have been classified as a Typic Ustifluent, Typic Ustipsamment, and a Typic Fragiorthod. Typically these soils have a brown gravelly loam surface and are underlain at varying depths by very gravelly loamy sand.

LA-2

BIOTA

A gross estimate of areas by SAF forest types (Society of American Foresters 1954) is as follows:

No.	Name	Area
227	Western Redcedar - Western Hemlock	184 ha. (455 acres)
226	Pacific Silver Fir - Hemlock	32 ha. (80 acres)
228	Western Redcedar	16 ha. (40 acres)
221	Red Alder	10 ha. (25 acres)

Much of the acreage of Pacific silver fir - hemlock type is composed of small patches and stringers of trees. In addition to the areas classed as forest, there are approximately 30 ha. (75 acres) of brushfields, 28 ha. (70 acres) of "barrens" — cliffs, meadows, and talus — and 18 ha. (45 acres) of water within the natural area. Küchler's (1964) Types 2 (Cedar-Hemlock-Douglas Fir Forest), 3 (Silver Fir - Douglas Fir Forest), 4 (Fir - Hemlock Forest), 25 (Alder - Ash Forest), and 52 (Alpine Meadows and Barren) are represented within Lake Twentytwo Research Natural Area. The natural area spans both the *Tsuga heterophylla* and *Abies amabilis* Zones of Franklin and Dyrness (1969) and includes many elements of the *Tsuga mertensiana* Zone in the lake basin.

The lower forests in the natural area are old-growth stands of western hemlock and western redcedar. Some Pacific silver fir (*Abies amabilis*) are present as well as an occasional Sitka spruce (*Picea sitchensis*) at lowest elevations. The largest trees are the redcedar which average 1.5 to 2.5 m. (5 to 8 ft.) in diameter (fig. LA-2), with a maximum of nearly 3.7-m. (12-ft.) d.b.h. Hemlocks of all ages and sizes up to 130-cm. (50-in.) d.b.h. are present. Western hemlock appears to be the climax species, as reproduction of western redcedar is generally absent and that of Pacific silver fir is sporadic at low elevations. The understory can be typified by *Vaccinium alaskaense*, *V. ovalifolium*, *Menziesia ferruginea*, *Blechnum spicant*, *Cornus canadensis*, *Rubus pedatus*, *Spaghnum girgensohnii*, and *Hylocomium splendens*. In wetter locations, e.g., along streams, *Oplopanax horridum*,

Athyrium filix-femina, *Rubus spectabilis*, *Tolmeia menziesii*, *Ribes bracteosum*, and *Boykinia major* are conspicuous.

Forests at higher elevations are characterized by Pacific silver fir, mountain hemlock (*Tsuga mertensiana*), and Alaska-cedar (*Chamaecyparis nootkatensis*). In older stands, the trees average 75- to 100-cm. (30- to 40-in.) d.b.h. The climax species appears to be silver fir, as reproduction of the others is sparse. A dense layer of shrubs is usually present, including *Vaccinium alaskaense*, *V. ovalifolium*, *Menziesia ferruginea*, *Rubus spectabilis*, and *Cladothamnus pyrolaeiflorus*. Dominant herbs are *Streptopus curvipes*, *Rubus pedatus*, *Blechnum spicant*, and *Maianthemum bifolium* var. *kamschaticum*.

Another major group of communities is brushfield stands; these vary in character depending on local moisture and temperature conditions. One type, conspicuous along the Lake Twentytwo Trail, is dominated by vine maple (*Acer circinatum*); it is found on scree slopes. Many other shrubs are present, such as *Rubus spectabilis*, Sitka alder (*Alnus sinuata*), *Sambucus* sp., *Ribes lacustre*, and *Oplopanax horridum*. The rich herb layer usually includes *Athyrium filix-femina*, *Pteridium aquilinum*, *Cryptogamma acrostichoides*, *Montia* spp., *Aruncus sylvestris*, *Galium* sp., and *Tolmeia menziesii*. A part of one vine maple-dominated brushfield includes a small stand of bigleaf maple (*Acer macrophyllum*) 20- to 25-cm. (8- to 10-in.) d.b.h. (fig. LA-2).

The cirque basin occupied by Lake Twentytwo is a mosaic of habitats and communities, mostly nonforested (fig. LA-2). Habitats include wet rocky cliffs, margins of permanent snowpatches, boulder fields, scree slopes, and alluvial deposits along the lake shore; all are supplied with abundant moisture. The communities include: a variety of dense herbaceous stands dominated by species such as *Polygonum bistortoides*, *Athyrium americanum*, *Carex* spp., *Veratrum viride*, *Valeriana sitchensis*, and *Caltha* sp.; dense shrub fields dominated by *Vaccinium ovalifolium*, *V. alaskaense*, *Menziesia ferruginea*, *Sorbus* sp., and *Cladothamnus pyrolaeiflorus*; and patches of mostly small Pacific silver fir, mountain

hemlock, and Alaska-cedar. Most communities have a distinctly subalpine aspect despite the 760-m. (2,500-ft.) elevation; *Phyllodoce empetrifolia* and *Luetkea pectinata*, timberline species, are found along the lakeshore.

A variety of fauna inhabit the natural area. A list of mammals believed to utilize the tract as residents or transients is provided in table LA-1. Fish were planted in Lake Twentytwo over 30 years ago; Wolcott (1961) indicates rainbow trout were planted in 1951.

The specialized terrestrial habitats have already been mentioned, e.g., the cliffs, snowpatches, and scree slopes of the lake basin. There is also the lake itself and the entire length of Twentytwo Creek (fig. LA-2).

HISTORY OF DISTURBANCE

The Lake Twentytwo area has a long history of public use and human disturbance is evident in a few locations. At one time there was a YMCA camp on the shore of the lake; it was abandoned and the debris removed prior to establishment of the natural area. The original trail to the lake closely followed the creek. It was abandoned when the present trail was completed but is still evident in some locations. At present the most obviously disturbed areas are around the lake, especially at the north end, where campers, hikers, and fishermen have created bare openings and a system of trails. Recreational use of the trail and lake margins is heavy and continuing.

There is no evidence of wildfire within the natural area, and none have been recorded within historic times.

RESEARCH

No research is presently being conducted within the natural area. Some unique research opportunities would include (1) comparison of the forests of Lake Twentytwo Research Natural Area with those on the south-facing Long Creek Research Natural Area 3 km. (2 miles) away, and (2) study of the relationships between plant and animal communities and the environmental mosaic within the Lake Twentytwo basin.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Granite Falls, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). Either the District Ranger (Monte Cristo Ranger District) or Forest Supervisor (Mount Baker National Forest, Bellingham, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Figure LA-1.— Lake Twentytwo Research Natural Area, Snohomish County, Washington.

Figure LA-2.—Natural features of the Lake Twentytwo Research Natural Area. Upper left: Typical specimens of old-growth western redcedar about 2.5-m. d.b.h. growing at lower elevations. Upper right: Lake Twentytwo Creek which is included almost entirely within the natural area. Lower left: Small stand of bigleaf maple (background) which averages 20- to 25-cm. d.b.h. and vine maple community (foreground) which dominates extensive areas of brushfields growing on talus. Lower right: A portion of Lake Twentytwo and the surrounding basin; note the persistent snowbanks in this later summer photograph.

LONG CREEK RESEARCH NATURAL AREA¹

Western hemlock, western hemlock - western redcedar, and climax red alder stands on a south-exposed mountain slope in the northern Cascades of Washington.

Long Creek Research Natural Area was established on January 2, 1947, as an example of virgin western hemlock (*Tsuga heterophylla*) - western redcedar (*Thuja plicata*) forest type. It complements Lake Twentytwo Research Natural Area, which is located on a north-facing mountainside 4 km. (2.5 miles) to the west. The 259-ha. (640-acre) tract is located in Snohomish County, Washington, and is administered by the Monte Cristo Ranger District (Granite Falls, Washington), Mount Baker National Forest. The natural area occupies the W1/2 of section 17 and E1/2 NE1/4, E1/2 SW1/4, and SE1/4 of section 18, T. 30 N., R. 9 E., Willamette meridian (fig. LC-1). It lies at 48°05' N. latitude and 121°41' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is via U.S. Highway 2 and State Highways 9 and 92 from Everett to Granite Falls and Forest Highway 7 to Verlot Ranger Station. Beyond the ranger station follow Forest Highway 7 east for 11.6 km. (7.2 miles) to Red Bridge Campground and turn left on Forest Road 3033. Beginning about 3.2 km. (2 miles) west of the junction, Road 3033

skirts the southern (lower) and, eventually, the western boundaries of the research natural area. In the near future a road providing access to the eastern boundary will be built. There are no trails or roads within the natural area boundary.

The nearest commercial overnight accommodations are in Everett about 56 km. (35 miles) away, although food can be obtained at Verlot and Granite Falls. There are seven public campgrounds within 3 to 14 km. (2 to 9 miles) of the natural area.

ENVIRONMENT

The Long Creek Research Natural Area occupies a portion of the south slope of Wiley Ridge. Elevations range from 1,100 m. (3,600 ft.) above sea level near the top of the ridge to about 380 m. (1,250 ft.) at the foot of the ridge near the South Fork of the Stillaguamish River. Topography is steep to very steep and broken on the slopes to gentle and rolling in the southern third of the area where the toe-slope of the ridge merges with the river terrace. One permanent stream, as well as approximately two-thirds of the Long Creek drainage, is almost entirely within the natural area.

The natural area is located on sedimentary bedrock of Pre-Middle Jurassic age (Hunting et al. 1961). However, this bedrock is covered by stratified glacial outwash of Pleistocene age on lower portions of the natural area. This outwash is of two types — a lower deposit of compact brown sands and gravels of glacial fluvial origin overlain by a deep deposit of blue-gray hard varved silt of glaciolacustrine origin.² The varved material con-

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

² Information from "Report on Slide on South-Fork Stillaguamish River at Gold Basin Forest Camp." Sept. 30, 1954, 10 p. Typewritten report by Shannon and Wilson, Consulting Engineers, Seattle, to State of Washington Department of Fisheries. (Copy on file Verlot Ranger Station, Granite Falls, Washington.)

sists of thin layers of silt, sand, and clay, horizontally bedded. Many of the beds are extremely unstable, especially when wet, resulting in slides and mudflows. The extensive mass land movements which characterize lower elevations in much of the natural area appear confined to this material.

A wet, cool, maritime climate characterizes the natural area. Annual precipitation is heavy and highly seasonal, although rain is not uncommon during the summer months, and summers are cool. Climatic data from the nearest weather bureau station (Darrington, Washington) about 19 km. (12 miles) north-east are as follows (U.S. Weather Bureau 1956, 1965). They probably approximate climatic conditions encountered at lower elevations in Long Creek Research Natural Area.

Mean annual temperature9.6°C. (49.4°F.)
Mean January temperature1.1°C. (33.9°F.)
Mean July temperature17.4°C. (63.3°F.)
Mean January minimum temperature-3.2°C. (26.1°F.)
Mean July maximum temperature25.9°C. (78.7°F.)
Average annual precipitation	...2,045 mm. (80.51 in.)
June through August precipitation154 mm. (6.06 in.)
Average annual snowfall120 cm. (47.4 in.)

Soils on the natural area have recently been mapped by U.S. Forest Service personnel as part of a soil survey of the Mount Baker National Forest (Snyder and Wade 1970). Soils on gently sloping terrain in the southern portion of the area are markedly unstable and are formed in deep glaciolacustrine deposits. These soils, classed as fine, mixed Andic Haplumbrepts, possess a brown silt loam to silty clay loam surface layer which grades into a slowly permeable silty clay subsoil at approximately 30 cm. (12 in.). On more steeply sloping terrain at intermediate elevations, mapped soils are coarse textured gravelly sandy loams over very deep deposits of very gravelly and cobbly sands. These are derived from marginal lake deposits and are classified as sandy, mixed Typic Ustifluent. In the northern section of the area, near Wiley Ridge, soils are derived from meta-sedimentary rocks and are classed as coarse loamy, mixed Typic Ferrosols. These soils have a dark reddish brown loam surface and are

underlain at about 55 cm. (22 in.) by dark yellowish brown very gravelly loam.

BIOTA

Estimated areas by SAF forest types (Society of American Foresters 1954), as determined from the most recent type map available, are:

No.	Name	Area
224	Western Hemlock	162 ha. (400 acres)
227	Western Redcedar - Western Hemlock	40 ha. (100 acres)
230	Douglas-Fir - Western Hemlock	40 ha. (100 acres)
221	Red Alder	16 ha. (40 acres)

Vegetation types present, according to Küchler's (1964) classification, would include: Type 2, Cedar - Hemlock - Douglas - Fir Forest; Type 3, Silver Fir - Douglas Fir Forest; and Type 25, Alder-Ash Forest. The natural area is mainly within the *Tsuga heterophylla* Zone (Franklin and Dyrness 1969).

Stands dominated by western hemlock cover the bulk of the natural area (fig. LC-2), but the age, structure, understory composition, number, and species of associated conifers vary greatly from site to site. On the slopes are stands of western hemlock mixed with varying proportions of western redcedar and scattered Douglas-fir (*Pseudotsuga menziesii*) and Pacific silver fir (*Abies amabilis*). Western hemlock is the major climax species, and many small openings are choked with dense hemlock reproduction (fig. LC-2). Hemlocks in one of the stands examined were about 175 years in age, 60-cm. (24-in.) d.b.h. (maximum 81-cm. or 32-in.), and 38 m. (125 ft.) in height. The understory can be typified by *Vaccinium alaskaense*, *Blechnum spicant*, and *Hylocomium splendens*. Other species commonly present include *Vaccinium ovalifolium*, *V. parvifolium*, *Cornus canadensis*, *Clintonia uniflora*, *Polystichum munitum*, and *Rubus pedatus*.

On some benches and the upper slopes of the natural area, mixed stands of Pacific silver fir and western hemlock are encountered in which the silver fir appears to be the major climax species. The understory is dominated

by *Rhytidiopsis robusta*, *Vaccinium alaskaense*, *Rubus pedatus*, *Cornus canadensis*, *Clintonia uniflora*, and *Blechnum spicant*. In one of these stands the 90- to 120-cm. (3- to 4-ft.) diameter and 61-m. (200-ft.) tall hemlocks and silver firs were estimated (from borings) to be over 400 years old.

Within the natural area are large old-growth Douglas-fir 180- to 200-cm. (70- to 80-in.) d.b.h. (fig. LC-2). They are concentrated in the northeast corner of the tract and on drier sites, e.g., around the steep slopes and cliffs in section 18. In the latter location the Douglas-fir is associated with an understory distinguished by the occurrence of *Berberis nervosa*, *Gaultheria shallon*, *Acer circinatum*, *Eurhynchium oreganum*, *Linnaea borealis*, and Pacific yew (*Taxus brevifolia*). Western hemlock is the major climax species.

Around streams, seeps, and similar moist habitats, a community dominated by large western redcedar and a dense understory of *Oplopanax horridum*, *Athyrium filix-femina*, *Blechnum spicant*, and many other herbs may be encountered. Very large redcedars are sometimes encountered on these sites.

A series of interesting red alder (*Alnus rubra*)-dominated communities are found on the unstable glacial deposits in the southern half of the natural area. The area appears to be a mosaic of stands of varying age and size depending upon when the last slump or landslide took place. Associated with the alder is black cottonwood (*Populus trichocarpa*), bigleaf maple (*Acer macrophyllum*), and Sitka spruce (*Picea sitchensis*). The understory includes species of *Petasites*, *Equisetum*, *Stachys*, *Galium*, and *Carex*, *Rubus spectabilis*, *R. ursinus*, *Oplopanax horridum*, and *Polystichum munitum*; and the rank growth obscures innumerable holes and erosion channels in the substrate. Older stands of red alder, Sitka spruce, bigleaf maple, and western redcedar are developing on small areas where the land surfaces have been stable for 30 to 50 years (fig. LC-2). Near the southern edge of the natural area a stand of stunted red alder, willow (*Salix* sp.), and dense *Scirpus* sp. has developed on alluvial deposits of the eroded glacial silts.

Red alder appears to be the likely climax species throughout most of this area. Constant disturbance of the land surface due to mass soil movements and erosion perpetuates the alder and prevents the stands from developing beyond this successional stage.

Mammals believed to utilize the natural area are listed in table LC-1.

Except for the stream sides and unstable land surfaces associated with the glacial deposits, no specialized habitats are known within the natural area.

HISTORY OF DISTURBANCE

There is no evidence of recent fires or human disturbance within the Long Creek Research Natural Area, although a small structure is shown in the SW1/4 of section 17 on the U.S. Geological Survey map of the Silverton Quadrangle. A small farm once existed adjacent to the southern boundary and National Forest lands adjacent to the west, south, and east boundaries are in process of being logged.

RESEARCH

No research is presently being conducted on the natural area. The mosaic of communities and environments on the unstable till deposits appears to offer unique research opportunities, perhaps even of geomorphologic phenomena.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Silverton, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1957; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). Either the District Ranger (Monte Cristo Ranger District) or Forest Supervisor (Mount Baker National Forest, Bellingham, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Snohomish County, Washington.

Figure LC-2.—Communities of the Long Creek Research Natural Area. Upper left: Typical stand of western hemlock averaging 45- to 70-cm. d.b.h. Upper right: Stand of red alder, Sitka spruce, bigleaf maple, and *Polystichum munitum* developed on portion of unstable glacio-lacustrine sediments at lower elevations. Lower left: Small opening in mature forest of western hemlock occupied by dense reproduction of western hemlock and small amounts of Pacific silver fir and western redcedar. Lower right: Group of large, old-growth Douglas-firs averaging 175- to 200-cm. d.b.h.

MAPLE KNOLL RESEARCH NATURAL AREA¹

Bigleaf maple and Oregon white oak stands on opposite slopes of a foothill ridge in Oregon's Willamette Valley.

Maple Knoll Research Natural Area was established on December 27, 1966. It provides stands of bigleaf maple (*Acer macrocarpum*) and Oregon white oak (*Quercus laevis*) stands typical of hilly areas in and adjacent to the Willamette Valley in western Oregon. The 4.5-ha. (100-acre) natural area is located in Benton County, Oregon, and is administered by the William L. Finley National Wildlife Refuge (Route 2, Box 208, Corvallis, Oregon), Bureau of Sport Fisheries and Wildlife. It is located in sections 31 and 32, T. 13 S., R. 5 W., Willamette meridian, 44°24' N. latitude and 123°20' W. longitude.

ACCESS AND ACCOMMODATIONS

The Maple Knoll Research Natural Area is located a short distance off U.S. Highway 101, about 16 km. (10 miles) south of Corvallis. An all-weather graveled road approaches within about 0.8 km. (0.5 mile) of the tract. It is bounded by a fire road along its northeastern edge, but this road cannot be used during winter months.

of approach. Commercial accommodations are available in Corvallis; there are no campgrounds available within the refuge.

ENVIRONMENT

The Maple Knoll Research Natural Area occupies both slopes (north and south) of the top of a low, east-west oriented foothill ridge (fig. MA-2). Slopes are gentle to moderate. Elevations range from about 168 m. (300 to 500 ft.). There are no streams or springs within the natural area. The area is located on low ground adjacent to the northern boundary.

The ridge occupied by the natural area is composed of light gray to yellowish arkosic micaceous sandstone with thin sandstone partings (Vokes et al. 1955). The material belongs to the Spencer formation of upper Eocene age. A narrow dike of granitic body of intrusive igneous rocks runs from east to west along the ridge line; the dike may be composed of basalt, granite, or diabase.

The natural area is located in western Oregon, an area of mild, moist climate. However, it is within the Willamette Valley, which is located between the Coast Range and the Cascade Ranges and is, therefore, subject to somewhat warmer and drier climate type than the interior western Oregon valleys. The dry period is especially pronounced. Representative climatic data from the nearest weather station are as follows (U.S. Forest Service Bureau 1965):

ing to a recent soil survey, two soil found within the natural area. The silty clay loam occupies the north the ridge, and the Dixonville silty occupies the ridge top and south the Dixonville series has been classified Brunizem and Pachic Ultic Argix- rding to the old and new soil classi- respectively. It consists of a well- silty clay loam surface soil over clay med in colluvium from basic igneous typical horizon sequence is as follows: k brown A1 from 0 to 13 cm.; very y brown A3 from 13 to 32 cm.; and t brown, clayey B2t from 32 to 66 cm. pine series (ex-Bellfountain soil ser- been classified as a Red-Yellow Pod- Typic Haploxerult. It consists of a ly deep silty clay loam surface soil and is typically formed in colluvium imentary rocks. A typical horizon is as follows: dark reddish brown 0 to 15 cm.; dark reddish brown B1 to 25 cm.; and dark red silty clay m 25 to 50 cm.

by vegetation types are as follows:

name	Area
ple forest	14 ha. (35 acres)
ite oak forest	18 ha. (45 acres)
	12 ha. (29 acres)

gon white oak stands can be assigned forest cover type 233, Oregon White iety of American Foresters 1954); ty does not recognize a type in which maple is the dominant species. The st can also be assigned to Kuchler's type 26, Oregon Oakwoods, and big- le stands are possibly assignable to

small in size averaging 25- to 40-cm. (10- 15-in.) d.b.h. Scattered through the tract older, larger specimens of grand fir (*Abies grandis*) which were not removed at the t of logging. Oregon white oak and Douglas (*Pseudotsuga menziesii*) are also encounter The trend of forest succession is not entire clear; grand fir and bigleaf maple are g erally both represented in reproductive classes.

The forest stands on the top and so slopes of the ridge are dominated by Ore white oak with a scattering of Douglas According to Anderson (1970), there i relatively dense canopy cover (80 perc and trees often exceed 18 m. (60 ft.) in hei Bigleaf maple are occasionally encounte in the south slope stands and, with Doug fir, appear to dominate reproductive classes.

Composition of the understory commu varies with aspect and strong changes the overstory. Bigleaf maple stands on north slopes typically have well-develo shrub and herbaceous layers. *Philadelph lewisii*, *Corylus cornuta* var. *californica*, Pacific yew (*Taxus brevifolia*) are com tall shrub species. *Polystichum muniti* dominates the herbaceous layer with a variety of associated herbs and mosses. understory in the white oak stands is ch acterized by the low shrub and liana spe *Rhus diversiloba*. The abundance of species is believed a consequence of he grazing (Thilenius 1964, 1968). Other un story species encountered include *Rosa eg* *tertia*, *Symphoricarpos albus*, and *Rubus sinus* in the shrub layer and *Galium* *Osmorhiza nuda*, *Satureja douglasii*, several perennial and annual grasses in herb layer. The oak stands relate to Thiler (1964, 1968) *Quercus garryana*/*Rhus dive*

are scattered through the grasslands. Animals believed or known to reside or pass through the Maple Knoll Research Natural Area are listed in table MA-1. The names of the oak stands are known in the literature (Anderson 1970). There are 15 species that inhabit the tract as permanent residents, in addition to seven occasional species, summer resident species, and three winter resident species. These include the hairy woodpecker (*Dendrocopos villosus*), downy woodpecker (*Dendrocopos pubescens*), black-capped chickadee (*Parus atricapillus*), white-breasted nuthatch (*Sitta carolinensis*), brown creeper (*Parus familiaris*), Bewick's wren (*Thryothorus bewickii*), robin (*Turdus migratorius*), vesper sparrow (*Vireo huttoni*), Rufous-sided towhee (*Pipilo erythrophthalmus*), and Oregon junco (*Junco oreganus*).

HISTORY OF DISTURBANCE

Human activities have had a strong influence on the development of existing forest communities within the Maple Knoll Research Natural Area. The stands on the north slope of the ridge were logged 30 or more years ago. Original stands were probably a mixture of Douglas-fir, grand fir, and bigleaf maple. Logging operations during the logging operations assisted in the conversion of the Douglas-fir and bigleaf maple. The Oregon white oak stands on the south slope of the ridge have probably never suffered significant logging. Hume, Habeck (1961, 1962) and Thilenius (1968) have provided abundant evidence that most of the closed canopy Oregon white oak stands in the Willamette Valley are a result of fire control activities instituted with the settlement of the valley in the late 1800's. Prior to this time, open oak savanna and grasslands were believed to

of introduced species. As mentioned, logging may also be one of the reasons for the abundance of *Rhus diversiloba* in the oak stands.

RESEARCH

The natural area has been used as a site for undergraduate research work by ecology and wildlife students from Oregon State University; the Refuge Manager can provide information. The south slope stands of Oregon white oak were one of five sampling sites used by Anderson (1970) in a study of fluctuating community composition and abundance of bird species in Oregon white oak stands.

Despite the disturbances by logging and grazing, the Maple Knoll Research Natural Area is a very valuable research tract. The communities are typical of many natural areas found in the Willamette Valley. Other protected sites of these types are extremely rare. Successional studies in the maple and grassland types seem especially appropriate to determine what effect human activities have had on them and how rapidly they are returning to a more natural state. That logging and grazing have been eliminated. Other opportunities include the study of changes in community composition, structure, and productivity on contrasting but adjacent topography and soils and of variations in animal populations and behavior in contrasting vegetation types.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include the following: *Topography* of Monroe, Oregon quadrangle, scale 1:50,000, issued by the U.S. Geological Survey in

MEEKS TABLE RESEARCH NATURAL AREA¹

**Ponderosa pine/pinegrass forest and
intermingled stiff sagebrush-grass
communities characteristic of the
eastern slopes of the Washington
Cascade Range.**

ne Meeks Table Research Natural Area
established in July 1948 to exemplify
derosa pine/pinegrass (*Pinus ponderosa*/
magrostis rubescens) communities and
ciated grasslands typical of the Cascade
ge in eastern Washington. The 27-ha.
acre) tract is located in Yakima County,
hington, and administered by the Naches
nger District (Naches, Washington), Sno-
mie National Forest. Its elongated oval
be is dictated by topography (fig. ME-1).
s located in sections 5 and 6, T. 15 N.,
4 E., Willamette meridian, at 46°15' N.
ude and 121°05' W. longitude.

CESS AND COMMODATIONS

he tract is located about 65 km. (40 miles)
hwest of Yakima and is approached via
Highway 410. Directions should be ob-
ed at the Naches Ranger Station for
tifying the graveled Forest Service roads
ne area and the trailhead location which
s to Meeks Table along a single, steep-

but becomes very difficult during
due to snow. Public accommodation
able in Yakima and Naches; primi-
camps are found in the vicinity
Table.

ENVIRONMENT

The Meeks Table Research Nat-
varies in elevation from 1,280 to
(4,200 to 4,525 ft.). Topographical
Table is an isolated flat-topped bu-
nant of a former basalt-capped plate-
150 m. (500 ft.) above the surround-
terrain. It is surrounded by precip-
with a 60- to 90-m. (200- to 300-f-
drop to talus slopes below.

A modified continental climate
Most precipitation occurs as snow
cool, cloudy winter. Summers
generally low in precipitation, a-
cloudless. One to 3 months of d-
common. Climatic data from Bum-
located in a valley 16 km. (10 m-
are as follows (U.S. Weather Bureau

Mean annual temperature 4.7
Mean January temperature - 4.9
Mean July temperature 14.5
Mean January minimum temperature - 10.0
Mean July maximum temperature 23.6
Average annual precipitation 1,214 mm
July through August precipitation 69 mm
Average annual snowfall 554 cm

It is undoubtedly much drier and
are warmer on the natural area it-

and conifer needle litter, covers the
Horizon sequences are:

5 cm.	Light gray ashy sand with little organic matter; pH 6.4.
20 cm.	Light brown loamy textured volcanic ash; crumb structure; abundant roots; pH 6.4.
45 cm.	Gritty clay with strongly developed nut structure and colloidal staining on cleavage surfaces; pH 5.8.
50 cm. +	Black fragmented clay; entire mass is dense waxy deposit.

gray, ashy sand observed by Rumars to be lenses of volcanic ash from the eruption of Mount Mazama St. Helens. In the IIBb horizons of glacial till have been observed, shallower, nonpodzolized soils (Regotisol) occur in areas of sagebrush which commonly have a biscuit-topography. These soils are stonier, lack the wind-deposited ash layers of prestored sites. The horizon sequence for a biscuit-type area is:

15 cm.	Light brown loam; friable crumb structure; 20 to 40 percent stone.
40 cm.	Brown gritty clay; cleavage planes show colloidal staining; 30 to 50 percent stone; pH 6.5.
0 cm. +	Moderately cracked bedrock of biabase material; slight lime depositions on rock surfaces.

little or no litter or organic layer

Name

Area

<i>Stipa columbiana</i> - <i>Phlox diffusa</i> - <i>Artemisia rigida</i>	10 ha. (25)
<i>Poa sandbergii</i> - <i>Eriogonum douglasi</i> - <i>Artemisia rigida</i>	4 ha. (11)
<i>Pinus ponderosa</i> / <i>Calamagrostis rubescens</i> - <i>Lupinus laxiflorus</i>	7 ha. (17)
<i>Pseudotsuga menziesii</i> / <i>Calamagrostis rubescens</i> - <i>Arnica cordifolia</i>	6 ha. (15)

The areas of *Pinus*/*Calamagrostis*-*Lupinus* can be assigned to SAF cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and Küchler's (1964) 11, Western Ponderosa Pine Forest. The areas of *Pseudotsuga*/*Calamagrostis*-*Arnica* can be assigned SAF forest cover type 214, Ponderosa Pine-Western Larch-Douglas-Fir, and Küchler's Type 12, Douglas Fir Forest. The grass-stiff sagebrush (*Artemisia rigida*) communities probably fall within Küchler's Type 55, Sagebrush Steppe. The entire area appears to fall within the *Abies grandis* zone found on the eastern slope of Washington Cascade Range (Franklin and Dyrness 1973).

The *Poa sandbergii*-*Eriogonum douglasii*-*Artemisia rigida* community is found on the north and south extremes of Meeks Ranch (figs. ME-2 and ME-3). These are harsh, rocky outcrops with little soil development and sparse vegetative cover (22 percent). Forbs and halfshrubs such as *Sedum spaldingii*, *Arenaria congesta*, and *Eriogonum douglasii* account for more than half of the vegetative cover (table ME-1). Sandberg grass (*Poa sandbergii*) and bottlebrush sage (*Sitanion hystrix*) are the most abundant perennial grasses. Cheatgrass (*Bromus tectorum*) is common in this community. Bitterbrush (*Purshia tridentata*) and sage comprise most of the shrub cover.

a-Phlox-Artemisia community are graded with bitterbrush occurring mainly in zone.

Stipa columbiana-Phlox diffusa-Artemisia is the most extensive community type (Meeks Table, occurring in large openings between the forested areas (figs. ME-2 and ME-3). Total vegetal cover is 41 percent. Cobble needlegrass (*Stipa columbiana*), pinegrass (*Calamagrostis rubescens*), and Sandberg bluegrass are the predominant grasses (table ME-1). Numerous forbs and halfshrubs account for more than half of the cover in the community. *Sedum* is the most common forb and *Phlox diffusa* the most common shrub. Small annual forbs such as *Collinsia heterophylla* and *Polygonum kelloggii* occur frequently. Stiff sage is the most common herb but accounts for only 10 percent of the total cover. This community resembles sagebrush-grass communities which have been protected by livestock overuse; however, livestock have never grazed Meeks Table. Within the community, there are areas resembling dune-swale topography with islands of pinegrass and bluebunch wheatgrass (*Agropyron subulatum*). Soil depth ranges from 6 dm. (2 ft.) to 2.7 m. (9 ft.). Soil bulk density and bulk weight are the highest of any of the communities (table ME-2). Contents of organic matter and total nitrogen are intermediate. Transition to forest communities is marked by an abrupt change in the topography of 15 to 30 cm. (6 to 12 in.) similar to the rise in the islands in the dune-swale topography.

The *Pinus ponderosa/Calamagrostis rubescens/Lupinus laxiflorus* community has a stocking rate of 91 trees per ha. (37 trees per acre). Of these, 80 are ponderosa pine and 11 are Douglas-fir (*Pseudotsuga menziesii*). Ponderosa pines average 64-cm. (25-in.) d.b.h., varying from sapling size to 162 cm. (64 in.)

geyeri) (table ME-1). These two species comprise two-thirds of the understory. *Pinus laxiflorus* is the most abundant. Soils are 3 to 5 m. (10 to 17 ft.) deep. The highest level of total nitrogen is found in the communities (table ME-2).

The *Pseudotsuga menziesii/Calamagrostis rubescens-Arnica cordifolia* community is derived from the *Pinus/Calamagrostis-Lupinus* community in composition and cover of the understory and understory and in stocking. Average number of trees per ha. is 100 (25 per acre) of which 234 (95 per acre) are Douglas-fir, 90 (36 per acre) are ponderosa pine, and the remainder are western white pine (*Larix occidentalis*) and grand fir (*Abies grandis*). Douglas-fir trees range in size from saplings to 117 cm. (46 in.), average 43 cm. (14 in.). Ponderosa pine, western white pine, and grand fir average 43-cm. (17-in.), 38-cm. (15-in.), and 13-cm. (5-in.) d.b.h., respectively. Reproduction of Douglas-fir and grand fir is good. Crown cover of trees ranges from 50 to 100 percent and averages 51 percent. Crown cover of understory is 10 to 100 percent such a high percentage of tree cover. Crown cover of understory is surprisingly high. Three-fourths of the crown cover is pinegrass and elk sedge (table ME-2). *Arnica cordifolia* is the predominant forb. Soil depth varies from 2 to 4.5 m. (6 to 15 ft.). Properties are similar to the soil of the *Calamagrostis-Lupinus* community. Bulk density and bulk weight that bulk density and total nitrogen are intermediate (table ME-2).

Both of the forested communities are probably occupying habitats analogous to the *Pseudotsuga menziesii-Calamagrostis rubescens* habitat type of Daubenmire (1968).

Mammals believed to utilize the area as residents or transients are listed in table ME-3.

Table ME-3. — Tentative list of mammals for Meeks Table Research Natu

Order	Scientific name	Common name
Insectivora	<i>Neotrichus gibbsi</i>	shrew mole
	<i>Scapanus orarius</i>	coast mole
	<i>Sorex cinereus</i>	masked shrew
	<i>Sorex obscurus</i>	dusky shrew
	<i>Sorex trowbridgii</i>	Trowbridge shrew
	<i>Sorex vagrans</i>	wandering shrew
Chiroptera	<i>Antrozous pallidus</i>	pallid bat
	<i>Eptesicus fuscus</i>	big brown bat
	<i>Lasionycteris noctivagans</i>	silver-haired bat
	<i>Lasiurus borealis</i>	red bat
	<i>Lasiurus cinereus</i>	hoary bat
	<i>Myotis californicus</i>	California myotis
	<i>Myotis evotis</i>	long-eared myotis
	<i>Myotis lucifugus</i>	little brown myotis
	<i>Myotis thysanodes</i>	fringed myotis
	<i>Myotis volans</i>	long-legged myotis
	<i>Myotis yumanensis</i>	Yuma myotis
	<i>Plecotus townsendi</i>	Townsend big-eared bat
	<i>Plecotus townsendi</i>	Townsend big-eared bat
Lagomorpha	<i>Lepus americanus</i>	snowshoe hare
	<i>Lepus californicus</i>	black-tailed jackrabbit
	<i>Lepus townsendi</i>	white-tailed jackrabbit
	<i>Ochotona princeps</i>	pika
	<i>Sylvilagus nuttalli</i>	mountain cottontail
	<i>Sylvilagus nuttalli</i>	mountain cottontail
Rodentia	<i>Clethrionomys gapperi</i>	Gapper red-backed vole
	<i>Erethizon dorsatum</i>	porcupine
	<i>Eutamias amoenus</i>	yellow-pine chipmunk
	<i>Eutamias townsendi</i>	Townsend chipmunk
	<i>Glaucomys sabrinus</i>	northern flying squirrel
	<i>Microtus longicaudus</i>	long-tailed vole
	<i>Microtus montanus</i>	mountain vole
	<i>Microtus oregoni</i>	Oregon or creeping vole
	<i>Neotoma cinerea</i>	bushy-tailed woodrat
	<i>Perognathus parvus</i>	Great Basin pocket mouse
	<i>Peromyscus maniculatus</i>	deer mouse
	<i>Sciurus griseus</i>	western gray squirrel
	<i>Spermophilus saturatus</i>	Cascades marmot
	<i>Spermophilus townsendi</i>	Townsend ground squirrel
	<i>Tamiasciurus douglasi</i>	chickaree
Carnivora	<i>Thomomys talpoides</i>	northern pocket gopher
	<i>Canis latrans</i>	coyote
	<i>Felis concolor</i>	mountain lion or puma
	<i>Lynx rufus</i>	bobcat
	<i>Martes americana</i>	marten
	<i>Mustela erminea</i>	short-tailed weasel
	<i>Mustela frenata</i>	long-tailed weasel
	<i>Taxidea taxus</i>	badger

Lower right: *Stipa-Phlox-Artemisia* community.

METOLIUS RESEARCH NATURAL AREA¹

Ponderosa pine forests on flat topography and steep westerly slopes typical of the east slope of the Cascade Range in central Oregon.

The Metolius Research Natural Area was established June 1931. It exemplifies ponderosa-bitterbrush (*Pinus ponderosa*/*Partridgebush*) on flats and ponderosa-Douglas-fir/green manzanita (*Pinus ponderosa*-*Pseudotsuga mucronata* / *Arctostaphylos patula*) on steep westerly slopes communities. These occupy extensive areas on the east slopes of the Cascade Range in central Oregon. The 581-ha. (1,140-acre) tract is located in Jefferson County, Oregon, and is administered by the Sisters Ranger District, Oregon, Deschutes National Forest. The rectangular area encompasses parts of T. 25, 26, 35, and 36, T. 12 S., R. 9 E., 11th meridian (fig. MI-1); boundaries are based on legal lines. It is located at 49° latitude and 121° 40' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is via U.S. Highway 20 and a forest road leading into the Metolius River drainage. The natural area is located about 29 km. (18 miles) northwest of Sisters and is most easily approached via U.S. Highway 20 and a series of paved forest roads. Access is good in summer, but snow creates difficulties in the winter. Public accommodations are available at Camp Sherman, about 2 km.

(1 mile) south of the tract, and at Sisters, Oregon; there are numerous improved forest campgrounds in the general area.

ENVIRONMENT

The Metolius Research Natural Area occupies two contrasting landforms; the western half is located on a nearly flat bench along the Metolius River and the eastern half occupies the very steep, west slope of Green Ridge. Elevations range from about 850 to 1,460 m. (2,800 to 4,800 ft.).

The geology of the natural area is strongly correlated with the topography. Bedrock in the western half is basalt and basaltic andesite lavas (Williams 1957). These Pleistocene-Recent materials belong to the High Cascade formation. The natural area actually straddles the Metolius fault and steep slopes in the eastern half of the tract are actually a fault escarpment. These slopes and Green Ridge itself are composed of Pliocene and Pleistocene olivine basalts and basaltic andesites of the High Cascades (Williams 1957). The surface of the entire natural area has 2 to 5 cm. (1 to 2 in.) of dacite pumice from ancient Mount Mazama and up to 7 cm. (3 in.) of basaltic ash from cinder cones to the east (Taylor 1968).

A modified continental climate prevails. Most precipitation occurs as snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Climatic data from Sisters, 22 km. (14 miles) southeast near the forest-steppe boundary, are as follows (West 1964):

Mean annual temperature 7.9° C. (45.5° F.)
Mean January temperature -0.5° C. (31.0° F.)
Mean July temperature 17.4° C. (63.4° F.)
Mean annual precipitation 408 mm. (16.07 in.)
June through August
precipitation 36 mm. (1.40 in.)

¹Information prepared by Dr. F. C. Hall, U.S. Forest of Agriculture, Forest Service, Region 6, Portland, Oregon.

area. Soils on the natural area have not been mapped or described. Throughout the tract, they are primarily dacite pumice and other aeolian volcanic ejecta of sandy loam to loamy sand texture over buried profiles. Minimal profile development is evident and would probably be classed as Regosol. A soil profile described on similar habitat a short distance away appeared as follows (West 1964):

0 5 to 10 cm.	Mull type humus from conifer and shrub litter.
A1 0 to 10 cm.	Dark brown (7.5 YR 4/4, dry) pumicy loamy sand; pH 7.3.
AC1 10 to 50 cm.	Strong brown (7.5 YR 5/6, dry) pumicy sand; pH 8.0.
AC2 50 to 132 cm. -	Brownish yellow (10 YR 6/6, dry) pumicy sand; pH 7.7; increasing size and density of gravel with depth.

BIOTA

Estimated area by plant community:

Name	Area
<i>Pinus ponderosa</i> Pseudotsuga	
<i>Pinus ponderosa</i> <i>Stipa occidentalis</i>	260 ha. (640 acres)
<i>Pinus ponderosa</i> <i>Arctostaphylos patula</i>	270 ha. (675 acres)
<i>Pinus ponderosa</i> <i>Abies grandis</i>	
<i>Pinus ponderosa</i> <i>Arctostaphylos</i>	51 ha. (125 acres)

The ponderosa pine communities can be assigned to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and to Küchler's (1964) Type 10, Ponderosa Pine Shrub Forest. The Douglas-fir-western larch (*Larix occidentalis*-ponderosa pine community probably relates to SAF type 214, Ponderosa Pine-Larch-Douglas-Fir, and to Küchler's Type 12, Douglas Fir Forest. Lower elevations in the area fall within the *Pinus ponderosa* Zone and higher elevations within the *Pseudotsuga* Zone or possibly *Abies grandis* Zone of north central Oregon (Franklin and Dyrness 1960).

The sole overstory dominant in the *Pinus*

bitterbrush (fig. MI-2). Herbaceous vegetation is scanty, consisting mostly of western needlegrass (*Stipa occidentalis*) with occasional bottlebrush squirreltail (*Sitanion hystrix*) and Ross's sedge (*Carex rossii*). It typifies key winter game range in this area.

The *Pinus*/*Arctostaphylos* community has overstory dominance of ponderosa pine but often has moderate to abundant Douglas-fir seedlings, saplings, and poles in the understory. Grand fir (*Abies grandis*) and incense cedar (*Libocedrus decurrens*) may also be present. Ground vegetation is dominated by green manzanita, often with abundant bitterbrush, western needlegrass, bottlebrush squirreltail, and Ross's sedge.

In the *Pseudotsuga* - *Larix* - *Pinus*/*Arctostaphylos* community, the pine and fir are mixed with moderate amounts of western larch in the overstory. Ground vegetation is dominated by green manzanita with western needlegrass, bottlebrush squirreltail, Ross's sedge and some *Fragaria cuneifolia*.

Mammals believed to reside in or visit the natural area are listed in table MI-1. Mule deer (*Odocoileus hemionus*) use the area as winter range.

HISTORY OF DISTURBANCE

Fire-scarred ponderosa pine and the absence of dominant, old-growth Douglas-fir and grand fir indicate ground fires periodically burned nearly all portions of the tract prior to initiation of fire control programs about 1910 (fig. MI-2). Fire scars record 10 to 12 ground fire occurrences.

Domestic livestock, mainly sheep, passed through the area on their way to grazing grounds at higher elevations in earlier years. They do not appear to have significantly altered the vegetation.

On the other hand, mule deer make heavy use of the lower bench area for primary winter range. Deer apparently have or are causing some changes in ground vegetation on the bench; bitterbrush is moderately to severely browsed and many ponderosa pine saplings are highlined.

merous studies have been carried out in vicinity of the natural area and are at least partially relevant there. They include: recent analyses of vegetation on the east slope of the central Oregon Cascade Range conducted by West (1964, 1968, 1969) and Swedberg (1961); studies of the flora and communities on Black Butte by Sherman and Johnson (1961); and Sherman's study of spatial and chronological changes in growth of bitterbrush as influenced by ponderosa pine overstory. Only Swedberg actually used the natural area as a study site, however.

Metolius Research Natural Area provides a variety of interesting research opportunities including: (1) determination of effects of game use on forested winter range used by mule deer; (2) evaluation of vegetation changes along topographic-vegetational gradient from a bench and up a steep, westerly slope;

cessation of natural ground fires; and (4) determination of influences of sharp topographic and elevational changes over short distances on biomass productivity.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area are: *Topography*—15' Sisters, Oregon and Whitewater River, Oregon quadrangles, scale 1: 62,500, issued by the U.S. Geological Survey in 1959 and 1961, respectively; *geology*—*Geologic Map of the Central Part of the High Cascade Range, Oregon* (Williams 1957), and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (Sisters Ranger District) or Forest Supervisor (Deschutes National Forest, Bend, Oregon) can provide details on the most recent aerial photo coverage of the area.

Lower right: Fire-scarred ponderosa pine located in flat portion of natural area; eight fires are recorded in this scar.

MILL CREEK RESEARCH NATURAL AREA¹

Transitional area between forest and grassland with mosaic of Oregon white oak, ponderosa pine, Douglas-fir and bunchgrass communities on the east slope of northern Oregon's Cascade Range.

The Mill Creek Research Natural Area was established on August 16, 1971, to exemplify the community mosaic found at the forest-grassland transition on the east slope of the northern Oregon Cascade Range. It contains representative, relatively undisturbed stands of bunchgrasses, Oregon white oak (*Quercus garryana*) with an understory of grasses and sedges, and Douglas-fir (*Pseudotsuga menziesii*) and ponderosa pine (*Pinus ponderosa*). The 330-ha. (815-acre) tract is located in Wasco County, Oregon, and is administered by the Barlow Ranger District (Dufur, Oregon), Mount Hood National Forest. The irregularly shaped tract is located in portions of sections 4, 8, 9, 16, and 17, T. 1 S., R. 11 E., Willamette meridian, at 45°30' N. latitude, 121°20' W. longitude (fig. ML-1).

ACCESS AND ACCOMMODATIONS

Since this natural area lies within the Mill Creek drainage, the municipal watershed of the City of The Dalles, access is strictly controlled. It is necessary to obtain permission for entry and, possibly, a key from the Ranger District before entering the watershed, regardless of the approach route. This is in addition

to obtaining permission to conduct research on the natural area itself.

The natural area is located about 27 km. (17 miles) west of Dufur, Oregon, and is approached by graveled county and National Forest roads. Dufur is 27 km. (17 miles) south of The Dalles on U.S. Highway 197. Access is good during the summer, but snow creates difficulties during the winter. Closest accommodations are in Dufur; developed forest camps are not convenient to the natural area.

ENVIRONMENT

The Mill Creek Research Natural Area varies in elevation from 790 to 1,040 m. (2,600 to 3,410 ft.). It is located on the gently to steeply rolling lower foothills of the east slope of the Cascade Range.

Parent rocks are grey hard basalt to grey to dark grey andesites. The area was glaciated during the Wisconsin period.

A modified marine climate prevails. Most precipitation occurs as rain or snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Winds are often strong, particularly during the winter since this area is located near the mouth of the Columbia Gorge. Climatic data from The Dalles, located along the Columbia River about 24 km. (15 miles) northeast and 700 to 800 m. below the tract, are as follows (U.S. Weather Bureau 1965):

Mean annual temperature 12.4°C. (54.4°F.)
Mean January temperature 1.1°C. (34.0°F.)
Mean July temperature 23.2°C. (73.8°F.)
Mean January minimum temperature -2.5°C. (27.6°F.)
Mean July maximum temperature 31.1°C. (88.0°F.)
Average annual precipitation 349 mm. (14.1 in.)
June through August precipitation 23.0 mm. (0.9 in.)
Average annual snowfall 6.0 cm. (23.5 in.)

¹ Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

When map can be examined at the Mount Hood National Forest headquarters or at the Dufur Ranger Station. Soils range from very shallow, slightly plastic cobbly loams overlying well-fractured, dark grey, hard basalt to moderately deep, slightly plastic, greyish loamy fine sands overlying grey to dark grey andesite. These materials are well drained, of moderately rapid permeableness and have weak surface stability.

BIOTA

Estimated areas by vegetation type are:

Name	Area
Forests of pole-sized Douglas-fir with mature ponderosa pine	166 ha. (410 acres)
Forests of Oregon white oak with mature ponderosa pine	126 ha. (310 acres)
Grassland	38 ha. (95 acres)
	330 ha. (815 acres)

The stands of Douglas-fir and ponderosa pine can be assigned to SAF forest cover type 214, Ponderosa Pine-Larch-Douglas-Fir (Society of American Foresters 1954), and Küchler's (1964) Type 12, Douglas Fir Forest. The Oregon white oak stands with ponderosa pine can be assigned to SAF type 333, Oregon White Oak, and to Küchler's Type 26, Oregon Oakwoods. The grassland areas can be assigned to Küchler's Type 51, Wheatgrass-Bluegrass.

Bunchgrass communities dominate steep to moderately steep southeast slopes and many ridge tops (fig. ML-2). These openings are characterized by bluebunch wheatgrass (*Agropyron spicatum*), arrowleaf balsamroot (*Balsamorhiza sagittata*), Idaho fescue (*Festuca idahoensis*), Sandberg bluegrass (*Poa sandbergii*), with some needlegrass (*Stipa* spp.) and cheatgrass brome (*Bromus tectorum*). These communities appear similar to those described for Daubenmire's (1970) *Agropyron spicatum*-*Poa secunda* habitat type, lithosolic phase, but apparently include more arrowleaf balsamroot.

Forests tend to form a complex pattern with the shallow soil grassland openings. Two kinds of the Oregon white oak stands can be distinguished: those dominated by smaller trees 10-cm. (4-in.) or less d.b.h. and those dominated by trees 15-cm. (6-in.) or more d.b.h., the latter including scattered ponderosa pine. Small diameter oak stands have a crown cover of 30 to 50 percent. Ground vegetation is dominated by *Elymus glaucus* with abundant *Symphoricarpos albus*, elk sedge (*Carex geyeri*), and various forbs. Oak stands of larger diameter trees have a crown cover of 20 to 30 percent and the oaks tend to occur in groups or clumps. Ground vegetation is dominated by elk sedge with bitterbrush (*Purshia tridentata*) and some *Amelanchier alnifolia*, needlegrasses, and bluebunch wheatgrass. In these areas, bluebunch wheatgrass tends to assume a rhizomatous habit. In general, Oregon white oak stands are located on southeast and southerly slopes from ridge-tops to the drainage bottom.

Stands dominated by Douglas-fir and ponderosa pine occur in swales and areas of deeper soil and on east and northeast slopes. Most ponderosa pine is mature to overmature and is generally over 50-cm. (20-in.) d.b.h., and 40 m. (120 feet) in height. The Douglas-fir is much younger and varies in diameter from 12- to 40-cm. (5- to 16-in.) d.b.h. Occasional grand fir (*Abies grandis*) and western larch (*Larix occidentalis*) are present. Ground vegetation is dominated by *Symphoricarpos albus*, elk sedge, occasional *Holodiscus discolor*, *Arnica cordifolia*, *Hieracium* spp., *Fragaria* spp., and other forbs.

A list of mammals believed to utilize the natural area as residents or transients is presented in table ML-1. Mule deer (*Odocoileus hemionus*) use the area as fall, winter, and spring range. Wild turkeys (*Meleagris merriami*) have been introduced in this area.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine indicate that ground fires periodically burned the area

cars. Some logging in the area occurred in the late 1800's. The area was also grazed, sometimes heavily, by domestic livestock prior to classification of the area as municipal watershed. No logging or grazing has been carried out for the past 60 years. The cheatgrass brome on a few of the steep south-facing grasslands suggests that vegetation has altered by grazing to at least some extent.

RESEARCH

No research is known on the area. It provides numerous interesting opportunities to study relationships between flora, fauna, plant communities, and environment within a mosaic of contiguous but very different kinds of vegetation—bunchgrass, Oregon white oak, and mixed conifer stands—in an area at the forest-grassland transition.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 7.5' Five Mile Butte, Oregon (scale 1:24,000), and 15' White Salmon, Oregon - Washington (scale 1:62,500) quadrangles issued by the U.S. Geological Survey in 1962 and 1967, respectively; and *Geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck

National Forest, Portland, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Figure ML-1.- Mill Creek Research Natural Area,
Wasco County, Oregon.

Figure ML-2.—Plant communities in the Mill Creek Research Natural Area. Upper left: Horizontal view showing natural grassland of bunchgrasses and arrowleaf balsamroot in the foreground and forest of small size Oregon white oak and *Elymus glaucus* in the middleground with stringers of the Douglas-fir-ponderosa pine forest. The mosaic pattern of plant communities is directly related to soil characteristics; shallower soils support the grasslands. Upper right: View from a community of bunchgrass and arrowleaf balsamroot across the Mill Creek watershed showing an Oregon white oak and elk sedge stand, with occasional mature ponderosa pine, and the upper edge of Douglas-fir-ponderosa pine stand. Center left: Small Douglas-fir with *Elymus glaucus*, *Symphoricarpos albus*, elk sedge, and forbs as ground vegetation. Center right: Larger, clumped Oregon oak with occasional mature ponderosa pine and ground vegetation dominated by elk sedge and some bitterbrush, *Amelanchier alnifolia*, needlegrass, and bluebunch wheatgrass. Lower left: Pole-sized stand dominated by Douglas-fir with occasional old-growth ponderosa pine and ground vegetation of *Symphoricarpos albus*, elk sedge, and forbs. This community is characteristic of ridges with deeper soil and east to northeast slopes. Lower right: Cove community of Douglas-fir and ponderosa pine with *Symphoricarpos albus*, *Holodiscus discolor*, sedge and forbs.

MYRTLE ISLAND RESEARCH NATURAL AREA¹

California-laurel with scattered old-growth Douglas-fir growing on a small island in the Umpqua River.

The Myrtle Island Research Natural Area established on September 14, 1951, to serve an old-growth stand of California-laurel (*Umbellularia californica*). The 11.3-ha. (acre) island is located in Douglas County, Oregon, and is administered by the Roseburg District (Roseburg, Oregon), Bureau of Land Management. The natural area occupies lot section 20 and lot 11 of section 21, T. 24 R. 7 W., Willamette meridian. It lies at 29' N. latitude and 123°34' W. longitude.

ACCESS AND ACCOMMODATIONS

Primary access is by State Highway 138 either Sutherlin or Elkton. Between July and September, the island can be reached from the north shore of the river by wading (MY-1). To reach the vicinity, leave State Highway 138 at Bullock Bridge, cross the bridge, and turn left on Cougar Creek Road. Drive along the river to the sign which marks the end of the county road (about 7.7 or 4.8 miles from the bridge); you are opposite Myrtle Island at this point. To approach the island by boat, leave State Highway 138 about 0.5 km. (0.3 miles) south of Bullock Bridge and drive along the Tyee Road

Description prepared by Dr. J. F. Franklin, Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

on the south side of the Umpqua River for about 7.9 km. (4.9 miles) to a short spur road down to the riverbank. A boat can be placed in the river at this site which is a short distance upstream from the island.

Travel on the island is not difficult although there are no trails.

The nearest commercial accommodations are in Sutherlin.

ENVIRONMENT

The Myrtle Island Research Natural Area is a typical river island with a series of more or less identifiable terrace levels. Topography is gentle with the only steep slopes located along the edge of the river or as short pitches between terraces. The elevation of the natural area is about 97.5 m. (320 ft.). The surface of the island varies from about 1.5 to 12 m. (5 to 40 ft.) above water level during the summer months.

The natural area is made up of fluvial deposits of gravel, sand, and finer materials. River action is constantly changing the form of the island, eroding it in some areas and depositing new materials in others.

The natural area is located in the mild, moist climatic region typical of western Oregon. However, it is within one of the valley systems located between the Coast Ranges and Cascade Range and is, therefore, subject to the somewhat warmer and drier climate typical of these areas. The summer dry period is especially pronounced. Representative climatic data from the Roseburg weather station, which is about 32 km. (20 miles) southwest are as follows (U.S. Weather Bureau 1965):

Mean annual temperature12.1°C. (53.7°F.)
Mean January temperature 5.2°C. (41.1°F.)
Mean July temperature19.9°C. (67.8°F.)
Mean January minimum temperature 1.6°C. (34.9°F.)
Mean July maximum temperature	..28.0°C. (82.4°F.)

temperatures are probably slightly lower and precipitation slightly higher on the natural area.

The soils on the natural area are all alluvial. They vary widely in stone content, texture, and depth. The best soils are found on the high terraces where stands of California laurel occur. The soils there are deep, loamy sands with no horizon development. Deposition of soil parent materials is still actively occurring all over the island. Recent depositions of coarse gravels and stones on the western point of the island and finer materials on the higher terraces probably occurred during floods in the winter of 1964-65.

BIOTA

Estimated areas by cover types are:

Name	Area
California-laurel-Douglas-fir	8.1 ha. (20 acres)
Other alluvial communities	3.2 ha. (8 acres)

The area seems to best fit Küchler's (1964) Type 29, California Mixed Evergreen Forest (*Quercus-Arbutus-Pseudotsuga*) and does lie within the Interior Valley (*Pinus-Quercus-Pseudotsuga*) Zone of Franklin and Dyrness (1969).

California-laurel is the most abundant single tree species present on the island. With Douglas-fir (*Pseudotsuga menziesii*) it forms dense forests on the upper, older island surfaces (fig. MY-2). Occasional bigleaf maple (*Acer macrophyllum*) and one or two western redcedar (*Thuja plicata*) and incense-cedar (*Libocedrus decurrens*) are also present. The stand in the eastern two-thirds of the forested tract has the largest and oldest trees with California laurel reaching 50- to 60-cm. (20- to 25-inches) d.b.h. and 15 to 21 m. (50 to 70 ft.) tall. The Douglas-fir average about 100-cm. (40-in.) d.b.h. and 38 to 46 m. (125 to 150 ft.) tall. The forest stand in the western third of the tract is composed of considerably smaller and younger trees.

The understory in the forested portion of

present include *Trientalis latifolia*, *Oxalis suksdorfii*, *Corylus cornuta* var. *californica*, *Acer circinatum*, *Galium triflorum*, and several species of grass. Strong successional trends are absent. Reproduction of the scattered old-growth Douglas-fir is lacking. Other tree species also do not appear to be reproducing beneath the dense canopy of California laurel. The only exception to this statement is in the California-laurel stand at the extreme eastern point of the island. In this localized area, reproduction of Oregon ash (*Fraxinus latifolia*) is scattered abundantly through the understory of *Rhus diversiloba* and *Polystichum munitum*.

A variety of open woodland, shrub, and weed communities occupies the western tip and northern shore of the island (fig. MY-2). These are for the most part lower lying areas which are subject to more frequent and severe disturbance by high waters. Included here is a stunted stand of Oregon white oak (*Quercus garryana*) and Oregon ash with a weedy understory; shrubby thickets of willows (*Salix* spp.) and white alder (*Alnus rhombifolia*); and a variety of herbaceous communities dominated by a rich collection of both native and alien grasses and weeds.

The mammals believed to utilize the natural area as residents or transients are listed in table MY-1. At one time, there was a small herd of wild angora goats which lived on the island but they are believed to have been eliminated by the flood of 1964. Several species of aquatic birds such as mallard ducks (*Anas platyrhynchos*) are found in the marshy areas adjacent to the northwest corner of the island.

HISTORY OF DISTURBANCE

Fire scars on old Douglas-fir indicate that ground fires have burned through at least part of the island sometime in the past. Axe marks also were noted in the bark of a few old-growth fir trees.

The entire island is subject to flooding

of 1961-63, an estimate of the island apparently under several feet of water. Massive disturbance of the vegetation and deposition of coarse materials occurred at the northern end of the island. This flood also damaged some of the southern banks of the island. Damage appears to have been minor to the California-laurel stands themselves though debris was lodged several feet up the branches of many trees and shrubs (MY-2).

RESEARCH

There is no research in progress on the Island Research Natural Area. As the only island in the regional research natural area system, it offers special opportunities to study soil and vegetation development in relation to geomorphological processes. The general sparsity of ground vegetation under the groves of California-laurel, coupled with the high content of aromatic compounds in leaves and litter of this species, suggests the area may also be a good field site for allelopathic studies.

MAPS AND AERIAL PHOTOGRAPHS

Topographic maps and most recent photographs available are the following: *Topography—Roseburg*, Oregon quadrangle, scale 1:62,500,

and *Geology—Geologic map of Oregon west of 121st Meridian*, scale 1:500,000 (Peck 1961). The District Manager (Roseburg District), Bureau of Land Management, can provide details on the most recent aerial photo coverage and forest type maps for the area.

NESKOWIN CREST RESEARCH NATURAL AREA¹

Sitka spruce and western hemlock
growing on a headland immediately
adjacent to the Pacific Ocean.

Neskowin Crest Research Natural
was established on October 26, 1941, as
a sample of Sitka spruce (*Picea sitchensis*)
and western hemlock (*Tsuga heterophylla*)
growing adjacent to the ocean. The
686-acre tract is located in Tillamook
County, Oregon, and is administered
by the Hebo Ranger District (Hebo, Oregon),
Columbia River National Forest. It is also a part of
the Cascade Head Experimental Forest, a
11,890-acre area maintained by the
Pacific Northwest Forest and Range
Experiment Station for research and demon-
stration of management techniques in coastal
hemlock forest (Madison 1957). The
area occupies all of section 2 except
the NW¹/₄ SW¹/₄ and the W¹/₂ W¹/₂
of section 1, T. 6 S., R. 11 W., Willamette
Meridian (fig. NC-1). It lies at 45°05' N.
latitude and 124°00' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is via U.S. Highway 101 between
Astoria and Neskowin. A maintained
Forest Road No. 1303, traverses the west half of the
natural area entering it from the south. To
reach this trail, turn west off U.S. Highway
101 into Forest Road S61 at the Cascade

Head summit. Continue on Forest Road S61
for about 6 km. (3.7 miles) to its junction
with Forest Road S61K. Turn right on Road
S61K and follow it for 0.3 km. (0.2 mile) to
the trail head. Trail 1303 enters the south-
western corner of the natural area about
1.6 km. (1 mile) from the trail head; the
entry point is presently unmarked. The
southeastern corner of the natural area can
conveniently be reached via Forest Roads S61,
S61J, S61B, and a short cross-country walk.
Follow Road S61 west for about 4 km. (2.45
miles) from U.S. Highway 101 and turn right
on Road S61J for 0.5 km. (0.3 miles) to reach
Road S61B. Leave Road S61B after approxi-
mately 0.3 km. (0.2 mile) and walk north-
westerly along a definite ridge top to reach
the natural area.

Numerous commercial accommodations
are available at Neskowin 1.6 km. (1 mile)
north and at Lincoln City, about 14 km. (9
miles) south. Neskowin Creek Forest Camp
is located along the Neskowin scenic drive
(old U.S. 101) within the experimental forest.

ENVIRONMENT

The Neskowin Crest Research Natural
Area is topographically rugged. It occupies
part of a headland which is dissected by
numerous drainages. Along the northwest
boundary, it plunges abruptly into the ocean
in a series of cliffs. Topography is gentle only
along major ridgetops; slopes are steep. Ele-
vations range from sea level to over 427 m.
(1,400 ft.) at the southeast corner. The tops
of the ocean cliffs — the lowest forested ele-
vations — are 45 to 75 m. (150 to 250 ft.) in
elevation. Numerous small permanent
streams rise within the natural area, and
drainages of several larger ones lie wholly or
predominantly within the natural area.

The natural area lies entirely on volcanic
bedrock, alkalic basalt flows, breccias, and

¹Description prepared by Dr. J. F. Franklin, U.S.
Department of Agriculture, Forest Service, Pacific
Forest and Range Experiment Station, Forest
Sciences Laboratory, Corvallis, Oregon.

materials are more resistant than surrounding sedimentary formations. However, there appears to be a capping of marine tuffaceous siltstone over the basalt bedrock in most locations; basaltic outcrops are generally confined to ocean cliffs.

The western Oregon marine climate is extremely pronounced in this oceanside natural area. It is wet and cool; seasonal and diurnal fluctuations in temperature are minimal. Strong ocean winds sweep the area. Although the bulk of precipitation occurs in the winter, a summer drought period is absent. A dominant climatic phenomenon is the summer fog which envelops the headland on most warm summer days. These fogs condense on tree crowns and fall to the ground as "fog-drip." A study of precipitation in forests and in openings on Cascade Head near the natural area indicated a 26-percent increase in precipitation under stands due to fog-drip (Ruth 1954). The following climatic data are from the nearest climatic station at experimental forest headquarters (listed as Otis 2 NE in U.S. Weather Bureau 1965):

Mean annual temperature13.3°C. (50.6°F.)
Mean January temperature 5.3°C. (41.5°F.)
Mean July temperature15.3°C. (59.6°F.)
Mean January minimum temperature 2.2°C. (35.9°F.)
Mean July maximum temperature	...20.9°C. (69.7°F.)
Average annual precipitation	...2,496 mm. (98.26 in.)
June through August precipitation 163 mm. (6.42 in.)

Additional climatic data for this station and the vicinity are available in Ruth (1954). Since the weather station is lower in elevation and farther inland, temperatures are probably somewhat cooler and precipitation higher (especially when fog-drip is included) on the natural area.

Soils in the natural area have not been mapped or classified into series; however, profiles examined can be best characterized as Astoria-like Sols Bruns Acides. They have developed primarily from tuffaceous siltstones

of the following horizons: 2- to 8-cm. 01 and 02; 5- to 10-cm. very dark brown silt loam A11; 7- to 23-cm. dark brown A12; 15- to 40-cm. dark yellowish-brown silty clay loam A3 or B1; 15- to 80-cm. dark yellowish-brown silty clay loam B2; and a B3 or C horizon, or both. Surface soils are strongly acid (e.g., pH 5.3), high in organic matter (e.g., > 20 percent) and total nitrogen (e.g., 0.50 percent), and low in percent base saturation (e.g., 10 percent).

BIOTA

Estimated area by SAF cover types (Society of American Foresters 1954) are:

No.	Name	Area
224	Western Hemlock	162 ha. (400 acres)
225	Sitka Spruce-Western Hemlock	105 ha. (259 acres)
223	Sitka Spruce	11 ha. (27 acres)

The area falls entirely within Küchler's (1964) Type 1, Spruce-Cedar-Hemlock Forest and the *Picea sitchensis* Zone of Franklin and Dyrness (1969).

Only two tree species are present in significant numbers — Sitka spruce and western hemlock. Occasionally red alder (*Alnus rubra*) and rarely Douglas-fir (*Pseudotsuga menziesii*) are encountered in the spruce-hemlock stands. Large old Sitka spruce, which average around 215-cm. (85-in.) d.b.h. and 73 m. (240 ft.) in height, are the most impressive specimens. These trees are over 250 years of age. The bulk of the forest is composed of spruce and hemlock about 120 years old, 75-to 100-cm. (30- to 40-in.) d.b.h., and 60 m. (200 ft.) tall (fig. NC-2). Over most of the natural area, both age classes are intermixed with old growth scattered through younger stands.

Successional processes are obvious throughout the natural area. Large old spruce are being windthrown or having their tops broken out. Large limbs broken from tops and windthrown trees showing extensive butt rot are

in hemlock; many open stands are d with hemlock poles and saplings (fig.). Under denser stands, the proportion nlock to spruce seedlings is even higher.

e composition of the understory is quite m throughout the natural area. *Mentha ferruginea*, *Polystichum munitum*, *Silene oregana*, *Maianthemum bifolium* var. *ochaticum*, *Montia sibirica*, and *Eurhynchium oreganum* are the constant and characteristic species (fig. NC-2). Less common s include *Vaccinium parvifolium*, *Clinocypus uniflora*, *Rubus ursinus*, *Melica subulacanthium ovatum*, *Tiarella trifoliata*, *Tiarella ovata*, *Galium triflorum*, and *Luzula saccata*. *Gaultheria shallon* is relatively mmon in the natural area, occurring y on rotten logs or stumps (fig. NC-2) t along the ocean cliffs where it is somean understory dominant. On the lower , along streams, and in seep areas, a tangle of shrubs and herbs develops, ing the following as well as the aforementioned species: *Oplopanax horridum*, *Sambucus spectabilis*, *R. parviflorus*, *Blechnum spaldingii*, *Ribes bracteosum*, *Dryopteris dilatata*, *Sambucus melanocarpa*, *Athyrium filix-femina*, *Disporum smithii*, and *Stachys americana*. *Carex obnupta*, *Corydalis scouleri*, *Thalictrum americanum*, and *Chrysosplenium angustifolium* typify swampy areas.

and forest openings are encountered are completely choked with shrubs such as *Sambucus spectabilis*, *Menziesia*, and *Sambucus racemosa* (fig. NC-2). Tree regeneration under these shrub layers is often sparse or absent.

e mammals which are known or probable inhabitants of the natural area are listed in fig. NC-1. A varied avifauna is associated with the ocean cliffs along the northwest boundary of the natural area, and northern raptors (*Eumetopias jubata*) frequent the open ocean.

Stream sides and ocean cliffs are the only worthy specialized habitats.

The dominance of 120 year-old spruce and hemlock indicates the area has been subject to at least occasional fires, the last major one occurring about 1845. During recent years, winter windstorms have been the most important agent of natural disturbance. Most of the damage has occurred along the southern boundary, but severe east winds in 1971 did break many old-growth Sitka spruce at 2 to 5 m. (6 to 15 feet) above ground line all through the natural area. There is no evidence of human disturbance in the natural area.

RESEARCH

Some observational research on the fauna and plant communities is currently being conducted on the natural area. At the time the natural area was cruised (1934), a map was prepared showing the location of all large Sitka spruce specimens. Copies of this map are on file at the Pacific Northwest Forest and Range Experiment Station.

The natural area and its environs do offer some special research opportunities. The natural area is adjacent to the Neskowin Crest Scenic Area, an oceanside strip of ocean cliffs, forest, and natural grassy openings which will be maintained in a near-natural state primarily for recreational purposes. The Nature Conservancy's Cascade Head preserve is also nearby. There is, therefore, the possibility of utilizing the natural area as a part of ecological studies on this oceanside complex. The flora and plant communities of a small natural headland prairie adjacent to the southwest edge of the natural area (Hart Cape) have already been studied (Davidson 1967).

Neskowin Crest Research Natural Area is also a part of the Cascade Head Experimental Forest, much of which is similar in forest type and environment. The possibility exists of using other parts of the experimental forest for work involving destructive sampling or manipulation and using the natural area as a control site.

area are: *Topography*—15' Hebo, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *geology*—*Geology of the Coastal Area Between Cape Kiwanda and Cape Foulweather, Oregon*, scale 1:62,500 (Snavely and Vokes 1949), *Geologic Sketch of Northwestern Oregon*, scale 1:500,000 (Snavely and Wagner 1964), and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (Hebo Ranger District) or Forest Supervisor (Siuslaw National Forest, Corvallis, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Copies of a topographic map (scale 8 in. = 1 mile, 50-ft. contour interval) of Cascade Head Experimental Forest, including Neskowin Crest Research Natural Area, which was prepared by Forest Service personnel in 1934, are on file at the Pacific Northwest Forest and Range Experiment Station, Portland, Oregon. Records of a 1934 cruise of the area and a map showing location of old-growth Sitka spruce are also on file there.

NORTH FORK NOOKSACK RESEARCH NATURAL AREA¹

slow-growth Douglas-fir, western
hemlock, and western redcedar
growing on steep mountain slopes
in the Northern Cascades of Wash-
ington.

North Fork Nooksack Research Natural Area was established on April 10, 1934. It is an example of the Douglas-fir (*Pseudotsuga menziesii*) - western hemlock (*Tsuga heterophylla*) forests found at midelevations in the Northern Cascade Range. The 605-ha. (150-acre) tract is located in Whatcom County, Washington, and is administered by the Glacier Ranger District (Glacier, Washington), Mount Baker National Forest. It is bounded on the south by State Highway 542, on the east by Welcome Creek, on the northern boundary line of sections 33, 34, and sections 26, 27, and 28, T. 40 N., R. 8 E., and on the west by the line between sections 1/2 and E1/2 of the NW1/4 of section 30, T. 40 N., R. 8 E. (fig. NF-1). The natural area therefore, includes parts of sections 33, 34, and 36, T. 40 N., R. 8 E., and section 30, T. 40 N., R. 8 E., Willamette meridian. It is located at 48°54' N. latitude and 121°45' W. longitude.

DESCRIPTION AND ACCOMMODATIONS

North Fork Nooksack Research Natural Area is reached via State Highway 542, the Mount Baker Highway. It lies about 16 and

Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Corvallis, Oregon.

51 km. (10 and 32 miles) east of Glacier and Bellingham, Washington, respectively.

The natural area has no trails or roads within its boundaries. State Highway 542 bounds it for about 5 km. (3 miles). Remnants of an abandoned way trail may be found along the west boundary. A logging road cuts diagonally for about one-fourth mile across the extreme southeast corner of the area. At present the only way to penetrate the area is by traveling cross country. Care is required because of rock bluffs and the steep slopes. High elevations in the eastern portion of the tract are best reached via the Welcome Pass trail about 1 km. (0.5 mile) to the northeast and cross-country travel through subalpine meadows to the natural area itself.

Commercial accommodations are available in Bellingham or, to a limited extent, at Glacier. There are several public campgrounds in the vicinity along State Highway 542.

ENVIRONMENT

The North Fork Nooksack Research Natural Area covers a broad elevational span on the steep, south-exposed slope of a major mountain ridge. Elevations vary from 580 m. (1,900 ft.) along the highway to over 1,585 m. (5,200 ft.) along the northern boundary in section 35. Steep, broken slopes of 40 to 80 percent or more are common. Rock bluffs and small benches are occasionally encountered. The largest areas of gentle topography are the benches along portions of the highway and another near the center of section 35. O'Leary Creek, flowing through a rocky drainage and avalanche track (fig. NF-2), bisects the natural area. Welcome Creek forms the eastern boundary. Numerous seep areas and intermittent streams are present.

Geologically, the natural area is reportedly composed of sedimentary rocks (graywacke, argillite, and siltstones) of Upper Jurassic and Lower Cretaceous age (Hunting et al.

area. A wet, cool maritime climate prevails. Annual precipitation is heavy with maxima in December and January and minima in July and August. Summers are generally cool with frequent cloudy days, but only about 10 percent of the annual precipitation occurs from June through August. Annual snowfall increases rapidly with elevation. Climatic conditions can be interpolated from data for the Glacier and Mount Baker Lodge stations, 13 km. (8 miles) west and 8 km. (5 miles) southeast, respectively (U.S. Weather Bureau 1956, 1965):

	Glacier R. S.	Mt. Baker Lodge
Elevation	286 m. (937 ft.)	1,266 m. (4,150 ft.)
Mean annual temperature	8.4°C. (47.2°F.)	4.5°C. (40.1°F.)
Mean January temperature	-0.3°C. (31.4°F.)	-2.6°C. (27.3°F.)
Mean July temperature ..	16.9°C. (62.5°F.)	12.1°C. (53.8°F.)
Mean January minimum temperature .	-4.0°C. (24.8°F.)	-5.7°C. (21.8°F.)
Mean July maximum temperature	24.7°C. (76.5°F.)	17.5°C. (63.5°F.)
Average annual precipitation	1,474 mm. (58.03 in.)	2,821 mm. (111.08 in.)
June through August precipitation	155 mm. (6.09 in.)	313 mm. (12.32 in.)
Average annual snowfall	106 cm. (41.9 in.)	1,398 cm. (550.3 in.)

Unpublished precipitation data for the Shuksan weather station, 0.8 km. (0.5 mile) east of the southeast corner of the natural area, can be obtained from the U.S. Weather Bureau.

Soils on the natural area have recently been mapped by U.S. Forest Service personnel as part of a soil survey of the Mount Baker National Forest (Snyder and Wade 1970). At lower elevations, along the southern boundary of the area, soils are derived

to sandy loam surface layer which grades into a very gravelly loamy sand subsoil at 55 to 75 cm. (22 to 30 in.). Soils in the northern portion of the area are classed as coarse loamy, mixed Typic Ferrosols. According to the map, the northeastern section is occupied by soils derived from metasedimentary or metavolcanic rocks, and the northwestern portion contains soils derived from highly fractured igneous rocks, such as andesite. These soils have dark reddish brown to brown loam surface layers underlain by very gravelly loam to sandy loam at depths ranging from 25 to 55 cm. (10 to 22 in.).

BIOTA

Areas by SAF forest types (Society of American Foresters 1954), so far as can be determined from the original inventory, are as follows:

No.	Name	Age	Area
230	Douglas-Fir — Western Hemlock	Old	195 ha. (482 acres)
230	Douglas-Fir — Western Hemlock	Young	54 ha. (133 acres)
227	Western Redcedar - Western Hemlock	Old	177 ha. (437 acres)
224	Western Hemlock	Old	120 ha. (296 acres)
221	Red Alder		2 ha. (4 acres)
			548 ha. (1,352 acres)

There are, in addition, 58 ha. (143 acres) classed as nonforested. This includes rock outcrops, subalpine meadow areas, and streamside brush fields. Vegetation types, as defined by Küchler (1964) appear to include: Type 2, Cedar - Hemlock - Douglas Fir Forest; Type 3, Silver Fir - Douglas Fir Forest; Type 4, Fir - Hemlock Forest; and Type 52, Alpine Meadows and Barren. The natural area spans three major vegetation zones (Franklin and Dyrness 1969) — the *Tsuga heterophylla*, *Abies amabilis*, and *T. mertensiana* Zones. The *T. mertensiana* Zone is most poorly represented occurring only at highest elevations.

The major tree species are Douglas-fir,

main hemlocks (*Tsuga mertensiana*) are located at highest elevations. Red alder (*Alnus rubra*) and black cottonwood (*Populus trichocarpa*) are sporadically represented in the riparian areas and along streams.

The bulk of the natural area is occupied by old-growth forests of Douglas-fir, western hemlock, and western redcedar growing on moderate to steep slopes. In these forests the Douglas-fir are scattered veterans with diameters of 175-cm. (50- to 70-in.) d.b.h. and ages of 600 years in age. These specimens are spaced five to 10 per acre and make up 30 percent of the forest volume. Western hemlock and western redcedar are more numerous, but they are generally smaller in diameter and younger. Succession in these forests is toward a climax forest of western hemlock. It is the only species reproducing in significant numbers (fig. NF-2). Typical understory species are *Polystichum munitum*, *Erigeron nervosa*, *Linnaea borealis*, *Pacific yew* (*Taxus brevifolia*), *Viola sempervirens*, *Chimaphila umbellata*, and *Pyrola asarifolia*. *Acer circinatum* is scattered but locally abundant. On driest slopes, *Pyrola asarifolia* and *Urtica dioica* are found.

Young-growth forests dominated by Douglas-fir and western hemlock occur as small patches and stringers. They are most abundant along the western edge of the natural area.

A different community is found on cool, moist benches at lower elevations within the natural area (fig. NF-2). The overstory consists of western hemlock, Douglas-fir, western redcedar, and Pacific silver fir. Reproduction of Douglas-fir, hemlock and Pacific silver fir indicate that the climax forest will include at least some of both. The understory is much more diverse including *Vaccinium alaskaense*, *Cornus canadensis*, *Rubus pedatus*, *Clintonia uniflora*, *Oplopanax horridum*, *Athyrium filix-femina*, *Blechnum spicant*, *Polystichum munitum*, *Tiarella unifoliata*, and *Gymnocarpium dioica*.

At higher elevations, within the *Abies* zone, the Douglas-fir and western

hemlock are typical. Pacific silver fir appears to be the climax species; hemlock reproduction is sparse. Typical understory species are *Cornus canadensis*, *Rubus pedatus*, *Clintonia uniflora*, *Vaccinium alaskaense*, and *Tiarella unifoliata*.

Finally, above about 1,375 m. (4,500 ft.), mountain hemlock replaces western hemlock as the major Pacific silver fir associate. These stands vary in understory characteristics from a relatively dense condition with well-developed, ericaceous shrub layers to a relatively open condition with a herbaceous understory. Subalpine meadows of varying type are associated with these stands but have not been examined in detail (fig. NF-2).

Mammals believed to utilize the tract as transients or residents are listed in table NF-1.

HISTORY OF DISTURBANCE

Human disturbance of the natural area has been and will probably continue to be minor because of its rugged and inaccessible character. Removal of dead or hazardous trees has been carried out along the highway. A short nature trail from the highway to the base of several large trees has periodically been opened and human visitation has been confined to a hectare or so in this vicinity.

Recent natural disturbances appear to have affected only limited areas within the tract. The occurrence of young stands of Douglas-fir indicates that portions of the natural area have been burned by wildfires during the last century. Avalanches have occurred in at least one drainage — that of O'Leary Creek.

RESEARCH

The North Fork Nooksack Research Natural Area has been used as a sampling site in a study of the amount and composition of forest floors under medium-altitude, old-growth coniferous forests in Washington (Gessel and Balci 1965). No additional research is presently known to be in progress.

major vegetation zones, also provides special opportunities for research concerned with environmental gradients.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Mount Shuksan, Washington, and Mount Baker, Washington, quadrangles, scale 1:62,500, issued by the U.S. Geological Survey in 1953 and 1952, respectively; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). Either the District Ranger (Glacier Ranger District) or Forest Supervisor (Mount Baker National Forest, Bellingham, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

OCHOCO DIVIDE RESEARCH NATURAL AREA¹

terior mixed conifer (ponderosa
ne, Douglas-fir, grand fir, and
western larch) forests and moun-
in meadows typical of central Ore-
n's Blue Mountains.

Ochoco Divide Research Natural Area
established in July 1935 to exemplify the
of ponderosa pine (*Pinus ponderosa*)
Douglas-fir (*Pseudotsuga menziesii*) and
and fir (*Abies grandis*), western larch
(*Larix occidentalis*), and Douglas-fir, char-
teristic of midelevations in the Blue Moun-
of central Oregon. The 777-ha. (1,920-
tract is located in Wheeler County,
, and is administered by the Big Sum-
anger District (Prineville, Oregon),
National Forest. Its roughly rectan-
shape includes portions of sections 28,
31, and 33 and all of section 32, T. 12 S.,
E., Willamette meridian. It is located
40' N. latitude, and 120°20' W. longi-
g. OD-1).

ESS AND MODATIONS

natural area is located about 48 km.
(30 miles) northwest of Prineville on U.S.
Highway 26 or about 14 km. (9 miles) north-
west of Ochoco Ranger Station on Forest
Roads 1222 and 1204. Forest Road 1204
runs through the southeastern corner of
the tract. Access is good during summer, but
creates difficulties during the winter.

¹Description prepared by Dr. F. C. Hall, U.S.
Department of Agriculture, Forest Service, Region 6,
Prineville, Oregon.

Public accommodations are available in Prine-
ville or in primitive forest camps in the
vicinity of the natural area.

ENVIRONMENT

The Ochoco Divide Research Natural Area
varies in elevation from 1,250 to 1,650 m.
(4,100 to 5,400 ft.). Topography varies from
undulating to rolling. The tract is located at
the upper edge of an uplifted plateau and is
underlain primarily by Clarno formation
materials (Baldwin 1964). These late Eocene
to early Oligocene deposits include rhyolite
and basalt flows, tuffs and breccias, as well as
some tuffaceous sedimentary rocks.

A modified continental climate prevails.
Most precipitation occurs as snow during the
cool, partly cloudy winter. Summers are
warm, generally low in precipitation and
largely cloudless. One to 3 months of drought
are common. Climatic data from Ochoco
Ranger Station located at 1,200 m. (3,980 ft.)
in a valley 11 km. (7 miles) to the southeast
are as follows (U.S. Weather Bureau 1965):

Mean annual temperature	6.2°C. (43.1°F.)
Mean January temperature	-4.3°C. (24.3°F.)
Mean July temperature	16.3°C. (61.4°F.)
Mean January minimum	temperature
.....	-9.9°C. (14.2°F.)
Mean July maximum temperature	27.8°C. (82.1°F.)
Average annual precipitation	490 mm. (19.3 in.)
June through August	precipitation
.....	76 mm. (3.0 in.)
Average annual snowfall	175 cm. (69.0 in.)

Precipitation is higher and temperatures
lower on the natural area itself.

Soils on the area have not been mapped or
described. Forest soils are developed from
aerially deposited volcanic ash over buried
soil profiles (Hall 1967). They resemble Gray
Wooded soils and are not podzolized.

Ponderosa pine forests	337 ha. (833 acres)
Grand fir - western larch - Douglas-fir forests	335 ha. (828 acres)
Wet and dry meadows	34 ha. (85 acres)
Grasslands	39 ha. (94 acres)
Western juniper - bunchgrass savannas	32 ha. (80 acres)

The distribution of these types is shown in figure OD-2. Ponderosa pine stands are generally assignable to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), although fir reproduction is common, and to Kuchler's (1964) Type 11 Western Ponderosa Forest. The mixed grand fir-western larch-Douglas-fir stands can be related to SAF type 213, Grand Fir - Larch - Douglas-Fir, and to Kuchler's Type 14, Grand Fir - Douglas Fir Forest. The western juniper (*Juniperus occidentalis*) stands can be assigned to SAF type 238, Western Juniper, and to Kuchler's Type 24, Juniper Steppe Woodland. The natural area is located within an *Abies grandis* Zone (Franklin and Dyrness 1969).

The forests dominated by old-growth ponderosa pine are also characterized by seedlings, saplings and sometimes poles of Douglas-fir, occasional western larch, and some grand fir. Ground vegetation is strongly dominated by pinegrass (*Calamagrostis rubescens*) (fig. OD-2). Other understory species are elk sedge (*Carex geyeri*), *Arnica cordifolia*, and *Lupinus* spp. Fire-scarred ponderosa pine are common. These stands have been classified as a mixed conifer/pinegrass community type by Hall (1967).

Grand fir - western larch - Douglas-fir stands are characteristic of north slopes. They vary in tree composition from nearly pure grand fir to a mixture of the three species. Ground vegetation is a moderately sparse stand of *Bromus vulgaris*, *Arnica cordifolia*, pinegrass, *Lupinus latifolius*, elk sedge, *Carex concinnoides*, *Hieracium albiflorum*, and *Pyrola* spp. Stands where larch is abundant contain fire-charred, dead, and downed

The western juniper communities occur on steep slopes and shallow soils (fig. OD-2). They are dominated by scattered western juniper with bitter cherry (*Prunus emarginata*), and Idaho fescue (*Festuca idahoensis*). Past livestock use and present game use of this highly palatable community have degraded the range to a point where it is considered in poor condition. Furthermore, the soils are shallow and recover very slowly following misuse.

The remaining grassland and meadow communities have not been extensively examined. One mountain meadow located in the southern half of the tract is dominated by *Poa pratensis* and *Bromus carinatus* with occasional *Veratrum californicum* and some *Cirsium vulgare*. Past livestock use has also altered vegetation in this meadow which might be considered to be in fair range condition.

Mule deer use the area as summer range. A complete list of mammals believed to utilize the natural area as residents or transients is provided in table OD-1.

HISTORY OF DISTURBANCE

Fire-scarred ponderosa pine indicate ground fires periodically burned the area prior to initiation of fire control programs about 1910. Hall (1967) has suggested that ponderosa pine/pinegrass communities constitute a fire climax which are shifting with fire control to grand fir and Douglas-fir climax. Dominance of fir reproduction in this plant community substantiates this hypothesis.

Some tree cutting, apparently for juniper fenceposts, occurred many years ago in the western juniper communities. A minor amount of timber was cut in connection with mining exploration work in the southwestern portion of the tract, the latest having occurred about 1966.

Domestic livestock grazed portions of the natural area between 1880 and 1963. Various segments of the tract were included in three grazing units — Nature Creek, Carrol Glade,

from about 1880 to 1920 with about 1000 head of sheep for four months of the year. Numbers were gradually reduced, and by 1930 to 1960 one band continued to use the area. Sheep and cattle grazed the Carroll Butte grazing unit from 1880 to 1962 when the unit was fenced off. This use of the area included in the grazing unit was fenced off. This use of the area included from 300 to 500 cattle from 1930 to 1962 and one band of sheep, between July and September 30 from 1940 to 1962. A driveway along the eastern edge of this unit had considerable influence on the pattern of grazing use. The Carroll Butte unit included about 400 acres of the area and, until 1960, had a pattern of use comparable to the Nature Creek unit. To summarize the effects of grazing, it appears to have affected the composition of the communities with a high proportion of palatable species, such as the western and moist meadow types. It does not appear to have severely affected ground vegetation or the forest communities.

Some claims in the southern half of the area suggest disturbance of soil and vegetation. However, these claims are not currently substantiated. The area has recently been withdrawn from general entry.

RESEARCH

Research is known to have been conducted within the natural area. However, communities similar to those found on the natural area were described and characterized in Hall's (1967) extensive study of the vegetation of the Blue Mountains.

The natural area provides interesting opportunities to evaluate: (1) biomass production affected by soils and topography under the macroclimate; (2) natural forest succession following control of ground fires; (3) the use and nongame animal habitat in the area of logging.

PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are sufficiently detailed to be useful. Either the District Ranger (Big Summit Ranger District) or Forest Supervisor (Ochoco National Forest, Prineville, Oregon) can provide details on the most recent aerial photo coverage of the area.

Figure OD-3.—Communities of the Ochoco Divide Research Natural Area. Upper left: Western juniper-bitter cherry/Idaho fescue community on shallow soil; vegetation has deteriorated from livestock and game animal use. Upper right: Moist meadow dominated by *Poa pratensis* and *Bromus carinatus* with some *Verbascum* and *Cirsium*; a deteriorated community resulting from past livestock grazing. Lower left: Ponderosa pine-grand fir/pinegrass community; pine dominates the overstory while fir dominates reproductive size classes. Lower right: Grand fir/pinegrass community approaching climax condition with dying Douglas-fir and sedge.

OLALLIE RIDGE RESEARCH NATURAL AREA¹

Subalpine mosaic of mountain meadows and true fir - mountain hemlock forest on some ridgetops in the western Cascades of Oregon.

The Olallie Ridge Research Natural Area was established on January 9, 1963, to provide examples of the mountain meadow and true fir (*Abies* spp.) - mountain hemlock (*Tsuga mertensiana*) communities found on high ridges in the western Cascades of Oregon. The 292-ha. (720-acre) tract is located in Lane County, Oregon, and is administered by the McKenzie Bridge Ranger District (McKenzie Bridge, Oregon), Willamette National Forest. The natural area is in two blocks each occupying the summit area of a ridgetop peak. The irregular boundaries (fig. OR-1) generally follow contour lines. The natural area is located in portions of sections 3, 4, 5, 8, 9, and 10, T. 17 S., R. 6 E., Willamette meridian, at 44°06' N. latitude and 122°05' W. longitude.

ACCESS AND ACCOMMODATIONS

The Olallie Ridge Research Natural Area can only be reached on foot. Several maintained trails penetrate or border portions of the tract. To reach the vicinity, turn south off of U.S. Highway 126 (McKenzie River Highway) onto the South Fork Road (Forest Road 1663). Follow this road and then the East Fork Road (Forest Road 1778) to the

trail heads for either Forest Trails 3326 or 3312, located on the slopes below the natural area. These trails provide the quickest access and require from 1 to 2½ miles of foot travel to reach the natural area.

The nearest commercial accommodations are at Blue River or McKenzie Bridge along U.S. Highway 126. There are numerous improved public campgrounds along the McKenzie River and the South Fork of the McKenzie River, as well as a primitive campsite in the saddle between the two units of the natural area.

ENVIRONMENT

The Olallie Ridge Research Natural Area occupies summits of two peaks on a major, north-south trending ridge (fig. OR-2). Slopes are generally steep to moderate, and rock outcrops are common. There are no permanent streams or ponds within the natural area. Elevations range from about 1,341 to 1,686 m. (4,400 to 5,530 ft.) at the summit of O'Leary Mountain in the west unit and from 1,463 to 1,725 m. (4,800 to 5,660 ft.) on the summit of Horsepasture Mountain in the east unit.

The natural area lies within a geologically older (Eocene to Miocene) part of the Cascade Range known as the western Cascades (Peck et al. 1964; Williams 1957). The pyroxene andesites which dominate belong to the Sardinia formation of Miocene age. Basalt, dacite, and various types of volcanic tuffs and breccias may also be present. Some data on lithology and petrography of the bedrock are found in Peck et al. (1964).

A cool, wet climate prevails. Summers are relatively dry; much of the heavy winter precipitation accumulates in snowpacks which probably attain maximum depths of 1 to 3 m. (3 to 9 ft.). The nearest climatic station (McKenzie Bridge) is at such a low elevation

¹ Description prepared by Dr. J. F. Franklin, U.S. Department of Agriculture, Forest Service, Pacific Northwest Forest and Range Experiment Station, Forestry Sciences Laboratory, Corvallis, Oregon.

natural area receives an average annual precipitation slightly in excess of 2,000 mm. (80 in.).

Soils in the natural area have not been mapped or described. Forest soils are typically weakly developed Brown Podzolics developed at least partially in surficial layers of aeolian-deposited volcanic ash. Soils under the non-forested communities tend to be shallow and stony.

BIOTA

Approximately 118 ha. (290 acres) of the Olallie Ridge Research Natural Area are occupied by nonforested communities, including both meadow- and shrub-dominated types. The remaining area can be assigned to SAF forest cover types (Society of American Foresters 1954) as follows:

No.	Name	Area
205	Mountain Hemlock - Subalpine Fir	130 ha. (325 acres)
229	Pacific Douglas-Fir	33 ha. (82 acres)
211	White Fir	9 ha. (23 acres)

Küchler's (1964) types represented include Silver Fir - Douglas Fir Forest (3), Fir - Hemlock Forest (4), and possibly, Grand Fir - Douglas Fir Forest (14), and Alpine Meadows and Barren (52). The natural area is located within the *Abies amabilis* Zone of Franklin and Dyrness (1969).

The most outstanding features of the Olallie Ridge Natural Area are the nonforested communities which occupy a variety of habitats and support a rich flora. During a study of disjunction and endemism, Hickman (1968) examined the vascular plant flora of over 42 peaks; he found that Horsepasture Mountain is one of the most floristically diverse areas in the entire western Cascades. Hickman provides a checklist of species found on both Horsepasture and O'Leary Mountains; it includes at least 30 disjunct species of phyto-geographic significance.

There are a variety of rock outcrop and meadow community types within the natural

alpine Xeric Meadow, Fine Gravel Scree, Outcrop Ridge, and Vertical Outcrop. Snowbed communities are found on outcrops or steep, open slopes of north aspect where snow accumulations reach considerable depth in winter. Characteristic species include *Claytonia lanceolata*, *Luetkea pectinata*, *Orogenia fusiforma*, *Erythronium grandiflorum*, and *Mertensia bella*. The Rocky Melt Seep community occurs where snowmelt trickles over rock outcrops, particularly on south-facing slopes; such habitats are dry after midsummer. Typical species include *Dodecatheon jeffreyi*, *Lewisia triphylla*, *Mimulus breweri*, *M. guttatus*, *Saxifraga occidentalis* var. *rufidula*, and *Gayophytum humile*.

The Wet Meadow community is one of the more extensive in the natural area. It is found on habitats with a constant moisture source and relatively deep soil. *Veratrum viride*, *Senecio triangularis*, and *Valeriana sitchensis* are characteristic dominants. Associated species include *Ribes bracteosum*, *Rubus spectabilis*, *Mitella breweri*, *Ligusticum grayi*, and *Hydrophyllum fendleri*, and *H. tenuipes*.

The Mesic Meadow community is also well represented. It is dominated by herbaceous perennials which have sufficient time to set seed in early summer before moisture supplies are exhausted. Typical dominants are *Rubus parviflorus*, *Pteridium aquilinum*, and *Rudbeckia occidentalis*. Associated species include *Erigeron aliceae*, *Lupinus latifolius*, *Ribes binominatum*, *R. viscosissimum*, *Polygonum phytolaccaefolium*, *Cirsium centaurea*, *Mertensia paniculata*, *Vicia americana* var. *truncata*, *Epilobium angustifolium*, and *Gayophytum humile*.

A third common meadow type is the Subalpine Xeric Meadow community which is found on habitats intermediate between the mesic meadows and the dry, rocky surrounding areas. Representative species include *Gilia aggregata*, *Collomia linearis*, *Gayophytum diffusum* var. *parviflorum*, *Orthocarpus imbricatus*, *Luina stricta*, *Polygonum minimum*, *P. douglasii*, *Navarretia divaricata*,

Thortus lobbi, *Rumex acetosella*, *Pachystima myrsinites*, *Amelanchier alnifolia* var. *semi-integrifolia*, and *Phacelia heterophylla*. A closely associated community is confined to ridges of rapidly weathering rock (Fine Gravel Scree). Many of the species common in the xeric meadow community occur here, as well as *Lotus nevadensis*, *Sedum oregonense*, and *Sanicula graveolens*.

Outcrop Ridge communities are found where mass wasting of small fragments has produced outcroppings of small patches of parent rock which are barely exposed and eroded parallel to the general slope of the area. Many species root in the weathered cracks of the outcrops or pockets of finer material: *Delphinium menziesii* var. *pyramidalis*, *Castilleja hispida*, *Penstemon procerus* var. *brachyanthus*, *Sedum stenopetalum*, *S. divergens*, *Eriophyllum lanatum*, *Arctostaphylos nevadensis*, *Haplopappus hallii*, *Silene douglasii*, *Comandra umbellata*, *Lomatium martindalei*, *Sanicula graveolens*, *Eriogonum umbellatum*, *E. compositum*, *Juniperus communis*, *Erigeron foliosus* var. *confinis*, *Arenaria capillaris* var. *americana*, *Erysimum asperum*, *Antennaria rosea*, *Phacelia heterophylla*, *Anaphalis margaritacea*, and *Penstemon cardwellii*. A few areas typifying the Vertical Outcrop community are present. Species adapted to these exposed environments include *Saxifraga bronchialis* var. *vespertina*, *Penstemon rupicola*, *Selaginella walacei*, *Erigeron cascadiensis*, *Polemonium pulcherrimum*, *Saxifraga caespitosa*, and *Heuchera micrantha*.

Tree species found within the natural area include mountain hemlock, Pacific silver fir (*Abies amabilis*), noble fir (*Abies procera*), western hemlock (*Tsuga heterophylla*), white fir (*Abies concolor*), subalpine fir (*Abies lasiocarpa*), and western white pine (*Pinus monticola*). All of the forests are relatively young in age (less than 130 years) and small in size; forest inventories of the area place all stands in either pole (maximum 28-cm. or 11-in. d.b.h.) or small sawtimber (maximum 53-cm. or 21-in. d.b.h.) size classes.

OR-2). Pacific silver fir appears to be the major climax species based on reproductive success in closed forest stands. The understory is typically poor in shrubs and relatively rich in herbaceous species. Common understory plants include *Achlys triphylla*, *Cornus canadensis*, *Clintonia uniflora*, *Pyrola secunda*, *Viola sempervirens*, *Rubus lasiococcus*, *Vaccinium membranaceum*, *Osmorhiza chilensis*, and *Arnica* sp.

On the dry, south-exposed slopes, forests are more typically dominated by Douglas-fir or white fir or both; Pacific silver fir often dominates the tree reproduction in these stands. Typical understory plant species include *Symphoricarpos* spp., *Chimaphila umbellata*, vine maple (*Acer circinatum*), *Pyrola picta*, *Rosa gymnocarpa*, *Pteridium aquilinum*, *Achlys triphylla*, *Smilacina sessilifolia*, and *Vaccinium membranaceum*.

In addition to meadows and forests there are significant areas occupied by shrub-dominated communities. These are typically found on wet sites adjacent to meadows or forests, on steep, north-facing slopes, and on talus associated with rock outcrops. Sitka alder (*Alnus sinuata*) is the common dominant on wetter substrates and north slopes where it forms dense thickets. Hickman (1968) considered this community to be a phase of his Wet Meadow type; they certainly are frequently associated with wet meadows and actually intergrade with them in some situations where the alder stems are more scattered. Deep winter snow accumulations and extensive snow creep cause strong bowing of the 3 to 5 m. (10 to 16 ft.) tall stems. In a nearby area the occurrence of these stands has been related to high soil water tables due to a nearly impervious subsoil², but in other regions they are associated with recurrent avalanches. Vine maple dominates the shrub communities on drier sites, and both species occasionally occur as codominants in mixed

² Unpublished soil survey data from the H. J. Andrews Experimental Forest on file at USDA Forest Service, Forestry Sciences Laboratory, Corvallis, Oregon.

The natural area is used as spring and early summer and fall range by blacktail deer (*Odocoileus hemionus columbianus*) and Roosevelt elk (*Cervus canadensis roosevelti*). Other mammals believed to occur within the natural area as residents or transients are listed in table OR-1.

HISTORY OF DISTURBANCE

The dominance of 130-year-old stands indicates the area has been subject to at least occasional fires, the last major one occurring in the mid-1800's. There are extensive areas of dead subalpine fir in and around the wet meadows which are probably the result of infestations of balsam woolly aphid over the last decade (Franklin and Mitchell 1967).

The natural area was intensively used as a sheep range until about the middle of the 1930's. There is still evidence of sheep camps around some grassy openings. Meadow composition has undoubtedly been strongly influenced by overgrazing of sheep.

RESEARCH

Extensive observations of the flora and plant communities of O'Leary and Horsepasture Mountains were made during Hickman's (1968) study of disjunction and endemism in the western Cascades of Oregon. His findings of floral diversity and community types have already been highlighted; for more complete information, see his original paper

collecting site in mycological studies.³ The Olallie Ridge Research Natural Area provides an unusual opportunity for studying subalpine meadow-forest mosaics. Possible studies include variation in community composition, structure, productivity, and succession in relation to environmental factors. It is also an important refugium for disjunct populations of numerous plant species.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area are: *Topography* — 15' McKenzie Bridge, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *geology* — *Reconnaissance Geologic Map and Sections of the Western Cascade Range, Oregon, North of Latitude 43° N.*, scale 1:250,000 (Peck et al. 1964), *Geologic Map of the Central Park of the High Cascade Range, Oregon* (Williams 1957), and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (McKenzie Bridge Ranger District) or Forest Supervisor (Willamette National Forest, Eugene, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the area.

PATAHA BUNCHGRASS RESEARCH NATURAL AREA¹

A grassland-forest mosaic of bluebunch wheatgrass and Douglas-fir communities located at the northern edge of the Blue Mountains in southeast Washington.

The Pataha Bunchgrass Research Natural Area was established in December 1968 as an example of mountain bunchgrass vegetation occurring at the transition from coniferous forest to steppe vegetation. The 20.7-ha. (51-acre) tract is located in Garfield County, Washington, and is administered by the Pomeroy Ranger District (Pomeroy, Washington), Matilla National Forest. It is located in the W ¼ of section 1, T. 9 N., R. 42 E., Willamette meridian, at 46°17' N. latitude and 117°30' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is via State Highway 128 from Pomeroy to the junction with Forest Road No. N-94 (Iron Spring Road), a distance of 22 km. (14 miles). Road N-94 passes along the eastern side of the tract (fig. PB-1). Access during summer is good but becomes difficult during winter. Public accommodations are available in Pomeroy or about 9 km. (6 miles) south of the tract at Big Springs Forest Camp.

ENVIRONMENT

The Pataha Bunchgrass Research Natural Area has a mean elevation of 1,372 m. (4,500

ft.) with a total variation of about 60 m. (200 ft.). Topography varies from flat to steep where it forms an upper part of the slope adjacent to Pataha Creek. The tract is located on the edge of a dissected plateau straddling the transition from the flat plateau top to steep canyon slopes. Columbia River basalts underlie the entire area. They have been uplifted and severely dissected by natural erosion.

A modified maritime climate prevails. Most precipitation occurs as snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Climatic data from Peola, located 3 km. (2 miles) to the north are as follows (U.S. Weather Bureau 1956):

Mean January temperature7°C.	(20°F.)
Mean July temperature20°C.	(65°F.)
Average annual precipitation584 mm.	(23.12 in.)
June through August		
precipitation100 mm.	(3.94 in.)
Average annual snowfall229 cm.	(90.00 in.)

Soils on the area have not been mapped recently; the Waha, Underwood, and Helmer soil series are possibly present (Washington Agricultural Experiment Stations 1954). Soil descriptions obtained at the time of the guidebook field examination are as follows:

(1) A shallow Lithosol with little profile development located on a plateau top of 0- to 5-percent slope and occupied by a bluebunch wheatgrass (*Agropyron spicatum*)-Idaho fescue (*Festuca idahoensis*) community:

A	0 to 15 cm.	Very dark brown (10 YR 2/2 moist, 2/3 dry) silt loam; slightly plastic, slightly sticky, with moderate, very fine subangular blocky structure; pH 6.7.
---	-------------	--

¹ Description prepared by Dr. F.C. Hall, U.S. Department of Agriculture, Forest Service, Region 6, Portland, Oregon.

Bedrock 25 cm. +

angular blocky structure; pH 6.7; 80- to 90-percent stone. Poorly cracked; evidence of restricted moisture drainage.

(2) A very shallow Lithosol with little profile development located on a 20-percent slope at the transition from plateau top to steep sideslope and occupied by a Sandberg's bluegrass (*Poa sandbergii*)-bluebunch wheatgrass community:

A	0 to 10 cm.	Dark brown (7.5 YR 2/2 moist, 3/2 dry) gravelly silt loam; slightly plastic, slightly sticky with weak, very fine granular structure; pH 6.8; 30- to 40-percent gravel.
B	10 to 20 cm.	Dark brown (7.5 YR 2/2 wet, 3/2 dry) very stony silt loam; slightly plastic, slightly sticky with weak, very fine granular structure; pH 6.8; 90- to 95-percent stone.
Bedrock	20 cm. +	Poorly cracked; evidence of restricted drainage.

(3) Profile with moderate development on steep (60- to 80-percent) southerly slope occupied by bluebunch wheatgrass community:

A	0 to 20 cm.	Dark brown (7.5 YR 2/2 moist, 3/3 dry) gravelly loam; slightly plastic, non-sticky with weak, very fine granular structure; pH 6.8; 30- to 40-percent gravel.
B	20 to 50 cm.	Dark brown (7.5 YR 2/2 moist, 3/2 dry) gravelly silt loam; plastic and slightly sticky with moderate, fine subangular blocky structure; pH 6.9; finely vesicular when dry; 20- to 40-percent stone, 20- to 30-percent gravel.
C	50 to 65 cm.	Dark brown (7.5 YR 3/2 moist, 4/4 dry) gravelly silt loam; plastic and slightly sticky with moderate, fine subangular blocky structure; pH 6.8; vesicular when dry; 20- to 40-percent stone, 20- to 30-percent gravel.
Bedrock	65 cm. +	Poorly cracked; evidence of clay depositions.

same as everything buried soils which appear similar to the grassland soils.

BIOTA

Estimated areas by community types are:

Name	Area
<i>Agropyron spicatum</i> / <i>Poa sandbergii</i>	13 ha. (33 acres)
<i>Pseudotsuga menziesii</i> - <i>Abies grandis</i> / <i>Vaccinium membranaceum</i>	7 ha. (18 acres)

The forest stands probably are assignable to SAF forest cover Type 210, Interior Douglas-Fir (Society of American Foresters 1954), and Kuchler's (1964) Type 14, Grand Fir-Douglas Fir Forest. The grasslands best fit Kuchler's (1964) Type 51, Wheatgrass-Bluegrass. The area would fall within a ponderosa pine (*Pinus ponderosa*) Zone if it were present in this area. However, most vegetation in the Blue Mountains is strongly affected by topography and soils, and this tract is an excellent example. South slopes represent an upper elevational extension of the bunchgrass steppe, and north slopes represent a lower elevational extension of fir forest.

Bluebunch wheatgrass dominates the bunchgrass stands (fig. PB-2). The relative position of wheatgrass in the plant community varies with soils and topography. On the plateau, it tends to dominate in both density and volume with Idaho fescue and Sandberg's bluegrass as constant and important associates. *Eriogonum heracleoides*, *Lupinus sericeus*, *Erigeron eatoni*, *E. bloomeri*, *Balsamorhiza serrata*, and *Achillea millefolium* are commonly present. On the transition from plateau to steep slopes, bluebunch wheatgrass codominates with Sandberg's bluegrass while *L. sericeus*, *E. eatoni*, *E. bloomeri*, and *B. serrata* are present. Bluebunch wheatgrass again dominates in both density and volume on steep south slopes. Sandberg's bluegrass and Idaho fescue are clearly subdominant in density and volume. Associated species are different, including *Berberis*

top, are generally absent. On the plateau top, the natural area contains a small example of grassland on rather deep soil, which Idaho fescue clearly dominates. Associated species are *Poa pratensis* and *Bromus tectorum*.

Most of the seven forested hectares (18 acres) represent seral stages of the *Abies grandis*/*Vaccinium membranaceum* association (Hall 1967). Douglas-fir (*Pseudotsuga muhlenbergii*) dominates the tree overstory with occasional ponderosa pine (fig. PB-2). Reproduction is largely grand fir (*Abies grandis*). Ground vegetation is dominated by *Vaccinium membranaceum* and pinegrass (*Calamagrostis rubescens*) associated with species such as elk sedge (*Carex geyeri*), *Hieracium biflorum*, *Lupinus latifolius*, and several well-developed colonies of the orchid *Cypripedium montanum*.

A *Pinus ponderosa*/*Calamagrostis rubescens* community forms an interrupted transitional band between grassland and Douglas-fir forest (fig. PB-2). Ponderosa pine clearly dominates and exhibits an open growth form without living branches extending within 3 m. (10 ft.) of the ground. Pinegrass strongly dominates ground vegetation, with other species such as *Spirea lucida*, elk sedge, *Lupinus latifolius*, and *Achillea millefolium* as common associates. Reproduction of Douglas-fir and grand fir is sporadic despite an abundant, adjacent seed source, suggesting this pine community is reasonably stable successionally.

Mammals believed to utilize the tract as residents or transients are listed in table PB-1.

Elk (*Cervus canadensis*) use the area as winter range and occasionally as spring or fall range during deeper snowfall. In general, they tend to move off the tract sufficiently early in the spring that grazing damage to grasses is prevented. Most forbs seem unavailable to elk in this area.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine indicate periodic ground fires prior to initiation of fire control programs in 1910. Lack of dominant

western larch (*Larix occidentalis*) suggests all portions of the forest have burned at some time. Sufficient grass volume is present on the grassland to carry a fire so one should assume it has been burned. Fire scars suggest the last fire was about 1890.

Domestic livestock grazed the tract to some extent between 1890 and 1945, when livestock numbers in the allotment were reduced. Topography and lack of water have precluded extensive or heavy livestock use. The area has probably not been significantly altered by grazing.

RESEARCH

Vegetation and soil descriptions and environmental notes for the grasslands on the plateau top, a steep south slope, and the transitional area are available.² Vegetation analysis utilized the "three step method" in which a 1.9-cm. or 3/4-in. loop is placed 100 times along each of two transects and on which vegetation or ground cover notes are made. Reconnaissance notes are also available for the forest vegetation.

The natural area provides interesting research opportunities on (1) effects of game use on bunchgrass vegetation; (2) factors responsible for the mosaic pattern of forest and nonforest communities; (3) variation in bunchgrass communities from flat plateau to steep slopes; and (4) biomass production as affected by soils and topography under a single macroclimate.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are sufficiently detailed to be useful. Either the District Ranger (Pomeroy Ranger District) or Forest Supervisor (Umatilla National Forest,

(12 to 18 in.) deep. Upper right: Topographic break from plateau to steep slopes occupied by community of Sandberg's bluegrass and low-density bluebunch wheatgrass growing on shallow soil 2 to 3 dm. (8 to 12 in.) deep. Lower left: Steep (60-percent), south slope occupied by bluebunch wheatgrass community with scattered Sandberg's bluegrass growing on deep, colluvial soil. Lower right: North-slope forest stand on *Abies grandis*/*Vaccinium membranaceum* habitat type with Douglas-fir, occasional ponderosa pine, and pinegrass.

PERSIA M. ROBINSON RESEARCH NATURAL AREA¹

Ponderosa pine and Douglas-fir forest characteristic of lower elevations on the east slope of the Oregon Cascade Range.

The Persia M. Robinson Research Natural Area was established in March 1948. It exemplifies the ponderosa pine (*Pinus ponderosa*) and mixed pine-Douglas-fir (*Pseudotsuga menziesii*) typifying the lower forest zone on the east slope of the northern Oregon's Cascade Mountains. The 118-ha. (540-acre) tract is located in Wasco County, Oregon, and is administered by Bear Springs Ranger District (Route 1, Box 65, Maupin, Oregon), Mount Hood National Forest. The essentially square area is located in sections 10 and 11, T. 6 S., R. 10 E., Willamette meridian, at 45°05' N. latitude, and 121°30' W. longitude (fig. PE-1).

ACCESS AND ACCOMMODATIONS

The natural area is located along U.S. Highway 26 about 35 km. (22 miles) southeast of Government Camp and 40 km. (25 miles) northwest of Warm Springs. The highway forms the eastern boundary of the tract. Access is good during both the summer and winter since snow is removed from the highway. Public accommodations are available at Government Camp or Warm Springs; there are several improved forest camps in the vicinity of the natural area.

¹ Description prepared by Dr. F. C. Hall, U.S. Department of Agriculture, Forest Service, Region Portland, Oregon.

ENVIRONMENT

The Persia M. Robinson Research Natural Area varies from approximately 850 to 950 m. (2,800 to 3,100 ft.) in elevation. Topography is undulating to rolling and is typical of lower foothills on the east slope of the Cascade Range.

The bedrock is composed of basalts and andesites, with andesitic flows probably predominant (Peck 1961).

A modified continental climate prevails. Most precipitation occurs as snow during the cool, cloudy winter. Summers are warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Unpublished climatic data collected at Bear Springs Ranger Station located 5 km. (3 miles) north of the natural area are on file there. No relevant published data are available. Isohyetal maps suggest around 900 mm. (35 in.) of annual precipitation.

Soils in the area have not been mapped. cursory examinations suggest aerically deposited pumicite is commonly mixed with residual materials.

BIOTA

Estimated areas by forest communities are:

Name	Area
<i>Pinus ponderosa</i> - <i>Pseudotsuga menziesii</i> / <i>Acer circinatum</i> / <i>Calamagrostis</i> <i>rubescens</i>	107 ha. (265 acres)
<i>Pseudotsuga menziesii</i> - <i>Abies grandis</i> / <i>Acer circinatum</i>	111 ha. (275 acres)

The ponderosa pine-Douglas-fir stands can be assigned to SAF forest cover type 214, Ponderosa Pine-Larch-Douglas-Fir (Society of American Foresters 1954) and Kuchler's Type 12, Douglas Fir Forest. Douglas Fir-grand fir (*Abies grandis*) stands probably belong to SAF type 213, Grand Fir-Larch-Douglas-Fir and Kuchler's Type 14, Grand

lin and Dyrness 1969).

Stand composition in this tract seems more closely related to ground fire history than to site variability (fig. PE-2). Stands currently dominated or codominated by ponderosa pine have minimal old-growth Douglas-fir. However, Douglas-fir seedlings and saplings are abundant and clearly dominate the smaller size classes; some poles are also present. Incense-cedar (*Libocedrus decurrens*) also occur occasionally. The understory in these communities is dominated by vine maple (*Acer circinatum*), *Symphoricarpos albus*, and *Ceanothus velutinus* in the shrub layer and pinegrass (*Calamagrostis rubescens*) and *Pteridium aquilinum* in the herb layer. Most of the *Ceanothus* is dead.

Douglas-fir-grand fir stands include occasional old-growth ponderosa pine in the overstory. Douglas-fir dominates the overstory and grand fir the seedling, sapling, and pole size classes. Western larch (*Larix occidentalis*) is sometimes a common stand constituent. Where crown cover of trees is dense, ground vegetation is minimal and typically composed of vine maple and pinegrass with occasional *Symphoricarpos*, *Pteridium*, and some forbs.

A list of mammals believed to utilize the natural area as residents or transients is provided in table PE-1.

HISTORY OF DISTURBANCE

Fire scarred ponderosa pine and western larch record periodic ground fires which

many portions of the tract have burned at some time.

Domestic livestock occasionally grazed the tract between 1890 and 1945 when livestock were removed from the general area. Cattle still drift into the area occasionally from adjacent lands. However, the natural area does not appear to have been significantly affected by grazing.

RESEARCH

No research is known on the tract. The natural area provides interesting opportunities to study: (1) forest succession in the absence of ground fires; (2) biomass productivity in undisturbed forest stands; and (3) stand structure and development in natural stands. Comparisons are possible with conditions on logged areas on adjacent National Forest and Indian Reservation land.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Mount Wilson, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956; and *geology* — *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Peck 1961). Either the District Ranger (Bear Springs Ranger District) or Forest Supervisor (Mount Hood National Forest) can provide details on the most recent aerial photo coverage of the area.

PIGEON BUTTE RESEARCH NATURAL AREA¹

Oregon white oak stands growing
on a low hill in Oregon's Willamette
Valley.

Pigeon Butte Research Natural Area was
published December 27, 1966, to exemplify
Oregon white oak (*Quercus garryana*) stands
typical of those found in western Oregon's
Willamette Valley. The 28-ha. (70-acre) tract
is located in Benton County, Oregon, and is
administered by the William L. Finley Na-
tional Wildlife Refuge (Route 2, Box 208,
Corvallis, Oregon), Bureau of Sport Fisheries
and Wildlife. The natural area is located in
Section 32, T. 13 S., R. 5 W., Willamette
County, at 44°24' N. latitude and 123°19'
longitude.

ACCESS AND COMMODATIONS

The natural area is found in the William L.
Finley National Wildlife Refuge which is
located about 16 km. (10 miles) south of
Corvallis, a short distance off U.S. Highway
101 (fig. PI-1). The natural area is located
about 0.2 km. (0.5 mile) from a graveled all-
weather road. Several dirt fire patrol roads
approach the tract. Visitors should inquire
at the Refuge headquarters about the best
time of approach. Numerous commercial
accommodations are available in Corvallis;
there are no campgrounds within the refuge.

Description prepared by Dr. J. F. Franklin,
Department of Agriculture, Forest Service,
Pacific Northwest Forest and Range Experiment
Station, Forestry Sciences Laboratory, Corvallis,
Oregon.

ENVIRONMENT

The Pigeon Butte Research Natural Area
occupies the northerly slopes of Pigeon Butte,
a relatively isolated hill rising 76 m. (250 ft.)
from the floor of the valley. All of the tract is
located on gentle to moderate slopes. There
are no streams or springs located within the
natural area. Elevations range from about 91
to 168 m. (300 to 550 ft.).

The natural area is located on a hill of
light gray to yellowish brown arkosic mica-
ceous sandstone surrounded by Willamette
Valley alluvium (Vokes et al. 1954). This
material belongs to the Spencer formation of
upper Eocene Age. A narrow dike or sill-like
body of intrusive igneous rocks (probably
basalt or gabbro) runs along the southern
boundary of the natural area from east to
west.

The natural area is located in western Ore-
gon, an area of mild, moist climate. However,
it is within the Willamette Valley, which is
located between the Coast and Cascade Ranges
and is, therefore, subject to the somewhat
warmer and drier climate typical of interior
western Oregon valleys. The summer dry
period is especially pronounced. Representa-
tive climatic data from the Corvallis weather
station, which is about 16 km. (10 miles)
north, are as follows (U.S. Weather Bureau
1965):

Mean annual temperature11.6°C. (53.0°F.)
Mean January temperature 4.1°C. (39.4°F.)
Mean July temperature19.2°C. (66.6°F.)
Mean January minimum temperature 0.6°C. (33.1°F.)
Mean July maximum temperature	27.1°C. (80.8°F.)
Average annual precipitation957 mm. (37.67 in.)
June through August precipitation 49 mm. (1.93 in.)

The soils within the natural area have
been mapped as the Dixonville silty clay
loam. This soil series has been classified as
a Brunizem and Pachic Ultic Argixeroll

formed in coniferium from oak forest. A typical horizon sequence is as follows: very dark brown A1 from 0 to 13 cm.; very dark gray brown A3 from 13 to 32 cm.; and very dark brown, clayey B2t from 32 to 66 cm.

BIOTA

Estimated areas by vegetation types are:

Name	Area
Oregon white oak closed forest	19 ha. (46 acres)
Oregon white oak savanna	7 ha. (18 acres)
Grassland	2 ha. (5 acres)

The areas of forest and savanna fit the Society of American Foresters (1954) cover type 233, Oregon White Oak, and K  chler's (1964) Type 26, Oregon Oakwoods. The natural area lies within the Interior Valley (*Pinus-Quercus-Pseudotsuga*) Zone of Franklin and Dyrness (1969).

The major tree species in the natural area is Oregon white oak (fig. PI-2). Anderson (1970) indicates that about 82 percent of the canopy cover is composed of this species. Dominant oaks typically range up to 60-cm. (24-in.) d.b.h. with occasional specimens exceeding 90-cm. (36-in.) d.b.h. Heights of dominants are generally from 18 to 21 m. (60 to 70 ft.). Other tree species present include bigleaf maple (*Acer macrophyllum*) and Pacific dogwood (*Cornus nuttallii*). Grand fir (*Abies grandis*) and Douglas-fir (*Pseudotsuga menziesii*) are extremely uncommon.

The closed canopy oak forests found on the natural area are probably of relatively recent origin. Habeck (1961, 1962) documents a major conversion of prairie and oak savanna to closed oak forest since settlement of the Willamette Valley. Fire control activities instituted by the settlers are believed responsible for this major successional change. Thilenius' (1964, 1968) detailed analyses confirm the fact that most Oregon white oak stands originated after 1850. Typically they are composed of scattered large trees of open-grown form and averaging 237 years old

large, old trees with the bulk of the stand made up of smaller oaks of forest-grown form.

Successional relationships within closed-canopy Oregon white oak stands are not clear (Franklin and Dyrness 1969). In the natural area bigleaf maple is the most conspicuous tree species in the reproductive size classes. Seedlings and saplings of oak are rarely found in closed canopy stands. Douglas-fir and grand fir, both of which have been suggested as climax species, are uncommon.

Most of the closed forest stands have relatively well-developed shrub and herb layers. Anderson (1970) describes a dense shrub layer averaging about 3,500 plants per ha. (1,400 per acre). *Corylus cornuta* var. *californica*, *Amelanchier alnifolia*, *Crataegus douglasii*, and *Osmaronia cerasiformis* are the most common tall shrubs. *Rhus diversiloba* is one of the most common low shrubs, and it is also conspicuous in a liana growth form. Thilenius (1964) has hypothesized that *Rhus diversiloba* is favored by grazing of oak woodlands because of interconnections between shrub and liana growth forms and its less palatable status. Other common low shrubs are *Rubus ursinus*, *Symphoricarpos albus*, and *Rosa nutkana*. Typical herbs are *Polystichum munitum*, *Pteridium aquilinum*, *Galium triflorum*, *Bromus laevipes*, *Montia sibirica*, *Hypericum perforatum*, *Lomatium utriculatum*, *Osmorhiza nuda*, *Satureia douglasii*, *Vicia americana*, and *Tellima grandiflora*. Most of the closed forest stands seem to best fit the *Quercus garryana*/*Corylus cornuta*/*Polystichum munitum* community described by Thilenius (1964).

The savannas of Oregon white oak have not been carefully examined. The understory is typified by an abundance of grasses and forbs including many introduced species. *Rhus diversiloba* is also conspicuous in parts of the savanna.

The grasslands are located mostly on the upper west and northwest exposed slopes of Pigeon Butte (fig. PI-1). Communities are

of *Eglanteria* and *Rhus diversiloba* are present. There is a high proportion of native species including all of the annual dominants. The grassland areas appear natural (as opposed to tracts created by early or latter-day farmers by clearing and burning). The composition has been strongly influenced by heavy grazing of domestic cattle and sheep. Successional status of the grasslands and savanna under the present system of fire control and no grazing is unknown.

Animals believed to reside within or to frequent the natural area are listed in Table I-1.

Anderson (1970) has provided a rather complete list of the bird species found on the natural area and data on seasonal fluctuations in their abundance. He lists 13 resident species, four occasional species, 13 summer residents, and 26 winter residents. Among the permanent residents are the hairy woodpecker (*Dendrocopos villosus*), downy woodpecker (*Dendrocopos pubescens*), scrub jay (*Sceloporus coerulescens*), blackcapped chickadee (*Parus atricapillus*), common bushtit (*Ampelis minimus*), white-breasted nuthatch (*Sitta carolinensis*), brown creeper (*Troglodytes familiaris*), Bewick's wren (*Thryothorus bewickii*), robin (*Turdus migratorius*), western-sided towhee (*Pipilo erythrophthalmus*), and Oregon junco (*Junco oreganus*).

HISTORY OF DISTURBANCE

Human activities have significantly influenced natural processes on the natural area. As mentioned, fire control activities have had upon settlement of the valley probably contributed to the development of the oak stands. The tract was heavily grazed by sheep and cattle until 1966. Some cutting of oaks was also carried out prior to establishment of the refuge. A rock pile is located on the south side of Pigeon

Butte, having a significant effect on the natural area itself, however.

RESEARCH

Several studies have been carried out within the Pigeon Butte Research Natural Area. The tract was used as a sampling site by Thilenius (1964, 1968) during ecological studies of Willamette Valley oak woodlands. Anderson (1970) used the natural area as one site in a study of bird fauna in Oregon white oak stands. Several classes in ecology and wildlife at Oregon State University, Corvallis, have utilized the natural area; details are available from the Refuge Manager.

The natural area is extremely valuable as a tract where near-natural communities typical of those found in the Willamette Valley can be studied; protected stands of Oregon white oak are extremely rare. Studies of the composition and structure and of successional and environmental relationships of Oregon white oak stands are especially appropriate. Since two natural areas representing other Willamette Valley vegetation types are nearby (Maple Knoll and Willamette Floodplain), it is also possible to use the tract as one site in studies concerning the entire valley mosaic.

MAPS AND AERIAL PHOTOGRAPHS

Special maps available include the following: *Topography* — 15' Monroe, Oregon quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1957; *geology* — *Geology of the West Central Border Area of the Willamette Valley, Oregon*, scale 1:62,500 (Vokes et al. 1954). Aerial photos taken in June 1970 may be purchased from the Agricultural Stabilization and Conservation Service, Benton County ASC Committee, P. O. Box 1027, Corvallis. Photo DFJ-1LL-49 provides the best coverage of the natural area.

ponderosa pine/bunchgrass on the
acially eroded Channeled Scab-
lands of east-central Washington.

Pine Creek Research Natural Area was
established in December 1966 to exemplify
a relatively undisturbed savanna of ponderosa
(*Pinus ponderosa*) and bunchgrasses
in the forest-grassland transition at the
eastern edge of eastern Washington's
scablands. The 65-ha. (160-acre) tract is located
in Spokane County, Washington, and is
administered by the Turnbull National Wild-
life Refuge (Route 3, Box 107, Cheney, Wash-
ington), Bureau of Sport Fisheries and Wild-
life. It is a long and narrow tract located in
T. 5 S., T. 22 N., R. 42 E., Willamette
County, at 47°25' N. latitude and 117°31'
W. longitude (fig. PN-1).

ACCESS AND ACCOMMODATIONS

To reach the natural area, travel south from
Cheney on the Cheney-Plaza county road for
4 miles (4 miles), then 3.2 km. (2 miles)
to the Refuge headquarters, where di-
rections will be provided. Access is
good during the summer and good during
winter. Public accommodations are avail-
able in Cheney.

ENVIRONMENT

Pine Creek Research Natural Area
elevation from 687 to 716 m. (2,250 to 2,350 ft.)

Description prepared by Dr. F. C. Hall, U.S.
Department of Agriculture, Forest Service, Region 6,
Spokane, Oregon.

in elevation. The undulating to rolling to-
pography is typical of the eastern Washington
Columbia Plateau.

The natural area is located on eastern
Washington's well-known Channeled Scab-
lands (Bretz 1959). The Columbia River ba-
salts which characterize the entire Columbia
Plateau provide the foundation of this land-
scape. An intricate network of drainage
channels is carved into this bedrock and an
overburden of loess. Glacial damming of the
Columbia River by a lobe of the continental
ice sheet is believed to have combined with
successive massive floods released from gla-
cially dammed lakes to produce the scablands.
The natural area itself does not appear to have
been directly glaciated.

A modified maritime climate prevails. Most
precipitation occurs as rain or snow during
the cool, cloudy winter. Summers are warm,
generally low in precipitation, and largely
cloudless. One to 3 months of drought are
common. Climatic data from Spokane, located
29 km. (18 miles) northeast of the site are as
follows (U.S. Weather Bureau 1965):

Mean annual temperature	8.8°C. (47.8°F.)
Mean January temperature	-3.7°C. (25.3°F.)
Mean July temperature	21.4°C. (70.5°F.)
Mean January minimum temperature	-7.7°C. (18.1°F.)
Mean July maximum temperature	28.7°C. (83.7°F.)
Average annual precipitation	437 mm. (17.2 in.)
June through August precipitation	56 mm. (2.2 in.)
Average annual snowfall	147 cm. (58.0 in.)

Soils in the area were mapped between 1955
and 1961. Complete information, using soil
names and descriptions approved in 1965, is
found in the Spokane County Soil Survey
(Donaldson and Giese 1968). Nearly all of
the soils in the natural area are mapped as
Hesseltine very rocky complex, 0- to 30-
percent slopes. This complex consists of from
25 to 50 percent of basalt rock outcrops and

STORY OF DISTURBANCE

Fire scars on ponderosa pine indicate fires periodically burned through the area prior to initiation of fire control programs.

This area has not been grazed, logged, or otherwise disturbed since establishment of the Refuge in 1937. However, stumps clearly show that much of the old-growth ponderosa pine was removed many years ago.

The presence and often dominance of cheatgrass and Japanese brome in many stands suggest that heavy livestock use prior to Refuge establishment has affected the vegetation, particularly in the more open plant communities; consequently, the area cannot be considered disturbed by livestock grazing. No other serious disturbances are known.

RESEARCH

Some research on the Pine Creek Research Natural Area is being conducted by ecology students at Eastern Washington State College, Cheney, Washington. Information on these investigations may be obtained from the Refuge Manager or from the Biology Department at Eastern Washington State College.

oucher specimens of some bird and animal species and most plant species are available at Refuge Headquarters for inspection.

The natural area provides interesting research opportunities on (1) natural development of plant communities without land treatment measures, a situation nearly impossible to find in this locality; (2) elevations of the interface between forest communities and nonforest, moist or wet marsh communities; and (3) evaluation of faunal activity in natural plant community lacking current

Refuge Manager (Turnbull National Wildlife Refuge, Cheney, Washington) for more details on the most recent aerial coverage of the area.

unnamed very stony, very shallow soils. The remainder of the complex is Hesseltine silt loam, a dry upland soil with topsoil up to 4 dm. (16 inches) thick underlain by gravel deposits to a depth of up to 15 dm. (60 inches) and basalt bedrock. Small areas of Cocollala silty clay loam, a poorly drained meadow soil, are also present. Hesseltine-type soils are associated with forest communities and meadows with the Cocollala type. Semiahmoo muck is found in the potholes.

BIOTA

Estimated areas by community are as follows:

Name	Area
<i>Pinus ponderosa</i> / <i>Festuca</i>	
<i>idahoensis</i>	54 ha. (135 acres)
<i>Populus tremuloides</i> meadow.....	8 ha. (20 acres)
Kettle lakes and potholes	2 ha. (5 acres)

The *Pinus/Festuca* communities are probably assignable to SAF cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954) and Küchler's (1964) Type 11, Western Ponderosa Forest. The meadows with quaking aspen (*Populus tremuloides*) can probably be classified as SAF type 217, Aspen. The area falls within a zone of ponderosa pine savanna at the transition from closed forest to steppe vegetation (Daubenmire and Daubenmire 1968).

The ponderosa pine forest is characteristically rather open with 25- to 40-percent crown cover and ground vegetation dominated by Idaho fescue (*Festuca idahoensis*) and cheatgrass (*Bromus tectorum*) (fig. PN-2). This plant community comprises 70 to 80 percent of the forested area. Other common understory species are *Bromus japonicus*, *Bromus tectorum*, *Bromus horridus*, *Bromus*

with a crown cover of 50 percent. The ground vegetation clearly dominated by grass (*Calamagrostis rubrescens*), Idaho fescue and *Stipa occiden-*
Symphoricarpos albus, *Potentilla*
tostaphylos uva-ursi. Soils are generally
topographic swales generally have a
layer of aerially deposited silt and clay
glacial outwash.

The *Pinus/Festuca* community is closely related with Daubenmire's *Festuca idahoensis* habitat. The *Pinus/Calamagrostis* stands are considered disjunct variants of *Pinus menziesii/Calamagrostis rubrescens* type (Daubenmire and Daubenmire 1968).

In a portion of the southern boundary natural area, stone polygons of deeper soil on which occasional pine may be found. The most common community found there is probably by dense stands of cheatgrass and very sparse cheatgrass. At least five species of lichens on exposed rocks. This plant community probably closely related to the phase of Daubenmire's (*Pinus spicatum/Poa sandbergii* habitat).

Much of the quaking aspen is as a border type or ecotonal community at the edges of meadows or swales.

A portion of the area of the lakes and potholes is covered by meadows dominated by *Phalaris* along with some *Deschampsia* (fig. PN-2). Most potholes in the area have standing water for most of the season and are dominated by *Scirpus acutus* (fig. PN-2) and/or *Scirpus acutus* (fig. PN-2) of the high water table and the matter content of the soil, particularly the muck (Donaldson and

Upper left: *Pinus ponderosa*/*Festuca idahoensis* stands with some cheatgrass are the most common community on gently mounded uplands; note exposed bedrock in background. Upper right: Network of stony soil surrounding mounds of deep soil; mounds dominated by cheatgrass; rocky areas support at least five species of lichen. Lower left: Moist meadow at southeast edge of the natural area dominated by *Phalaris arundinacea*. Lower right: *Scirpus* marsh near center of the tract which has seasonal standing water; quaking aspen occurs along the edges.

PORT ORFORD CEDAR RESEARCH NATURAL AREA¹

Port-Orford-cedar and Douglas-fir
growing on a rugged, geologically
diverse site on the southwestern
Oregon Coast Ranges.

The Port Orford Cedar Research Natural
Area was established on October 26, 1937,
as a preserve of virgin old-growth Port-Orford-
cedar (*Chamaecyparis lawsoniana*). The 454-
1,122-acre tract is located in Coos
County, Oregon, and is administered by the
Forest Ranger District (Powers, Oregon),
U.S. National Forest. The natural area
lies in section 35, a portion of the E½ of
T. 34 located south of Johnson Creek,
part of section 26 located south of John-
son Creek and west of the Coquille River,
and a small part of section 36 which lies
east of the Coquille River, all in T. 32 S.,
R. 12 W., Willamette meridian (fig. PO-1).
Coordinates are 42°45' N. latitude and 124°05'
W. longitude.

ACCESS AND ACCOMMODATIONS

Primary access is via Powers, Oregon,
which lies 29 km. (18 miles) south of State
Highway 42 on State Highway 242 and about
48 km. (21 and 30 miles) from Myrtle

Point, Oregon. The natural area
can be reached from Gold Beach on U.S.
Highway 101 by traveling east along the
Coquille River to Agness and then north on
Forest Road 333.

There are no roads or trails within
the Port Orford Cedar Research Natural
Area, although remains of an old trail can be
seen along part of the southern boundary. Entry
into the area is difficult, involving
bush-whacking or wading. For access to
the southeast and eastern portions of the
natural area, cross the bridge at Ferris Fork
Forest Camp (opposite Daphne Grove Forest
Camp) and hike uphill along the south boundary
for several hundred yards and penetrate
the natural area at or above the 380 m.
(1,280 ft.) contour. To reach the southwestern
portion and upper slopes of the natural area,
travel on Forest Road 333 south past Daphne
Forest Camp, thence on Forest Road 333 to
the head of Jim Hayes Creek and then up
the ridge, and walk north through a
creek into the natural area. Access is also
possible by fording Johnson Creek (easiest
approach) from Forest Road 326 or the
Fork of the Coquille River from Road 333.

The nearest commercial accommodations
are in Powers, Myrtle Point, Coquille
River, and Gold Beach. However, there are sev-
eral improved forest camps along Forest Road
333 in the vicinity of the natural area:
Daphne Grove, Myrtle Grove, and Boundary.

ENVIRONMENT

materials (sandstones, shales, and conglomerates) make up most of the bedrock. The bulk of these belong to the Galice Formation which consists of "Dark gray to black argillite and fine to medium grained sandstone with minor amounts of conglomerate containing sedimentary clasts. . ." (Baldwin and Hess 1971). This formation is Upper Jurassic in age. The contact line between this formation and the Middle Eocene Umpqua Formation (middle member) occurs along a fault line which runs north and south along the eastern edge of the natural area. Diller's (1903) mapping indicated the Tyee Formation contacted the Galice Formation directly in this area but this has been corrected by Baldwin and Hess (1971). An intrusion of gabbro covers about 40 ha. (100 acres) in the southeast corner of section 35. An extensive outcropping of serpentinite occupies the northeastern point of the natural area, and recent geological mapping of the Powers Quadrangle (Baldwin and Hess 1971) suggests this body extends much further south in the natural area than Diller (1903) indicates. Finally, a small outcrop of chert is located in the northwest corner of the natural area along Johnson Creek.

The climate is wet and mild. Precipitation is seasonal, with a peak in January and December and a minimum in July and August. The summer drought period is more pronounced than in the northern Oregon and Washington coastal mountains. The following climatic data are from the closest weather station at Powers (U.S. Weather Bureau 1965):

Mean annual temperature	12.0°C.	(53.6°F.)
Mean January temperature	6.6°C.	(43.8°F.)
Mean July temperature	17.6°C.	(63.6°F.)
Mean January minimum temperature	1.6°C.	(34.8°F.)
Mean July maximum temperature	25.0°C.	(77.0°F.)

Soil profiles are not described in the area although soils are of surveys are not available, but tend toward Reddish-Brown I 5 to 10 cm. (2 to 4 in.) thick A Brown Podzolics with minimal humus and weak B2ir horizon on steep slopes and ridgetops, A1-AC-C horizon sequences are

BIOTA

Estimated areas by SAF community of American Foresters 19 type 231, Port-Orford-Cedar 328 ha. (810 acres), and type Douglas-Fir, 126 ha. (310 acres) falls within Küchler's (1964) Hemlock-Douglas Fir Forest *heterophylla* Zone of Franklin (1969).

Douglas-fir (*Pseudotsuga*) and Port-Orford-cedar are the most tree species present, composing 75 and 25 percent, respectively of growth forests which dominate PO-3). Grand fir (*Abies grandis*), hemlock (*Tsuga heterophylla*), cedar (*Thuja plicata*), sugar pine (*Pinus lambertiana*), western white pine (*Pinus monticola*), and Pacific yew (*Taxus*) are also present. Hardwoods are represented although not usually above canopy level. Tanoak (*Lithocarpus*), golden chinkapin (*Castanopsis*), *phylla*), and Pacific madrone (*Arbutus ziesii*) are most abundant and occurrences of bigleaf maple (*Acer lum*), Oregon ash (*Fraxinus*), alder (*Alnus rubra*) and *C. (Umbellularia californica)* are Most of the natural area is

3 m. (175 ft.) tall and 100-cm. (40-in.). The largest Port-Orford-cedar measured g a 1936 cruise was 208.3-cm. (82-in.)

variety of plant communities are found in the natural area. Typically, the stands have a dense understory of shrubs and small trees, such as *Rhododendron macrophyllum*, *Pinus parvifolium*, *V. ovatum*, tanoak, western chinquapin, *Gaultheria shallon*, and *Berberis nervosa*. *Rhododendron* may attain heights of 8 m. (25 ft.) and diameters of 15 cm. (4 to 6 in.). Herbaceous species include *Polystichum munitum*, *Galium trincavi*, *Oxalis oregana*, *Viola sempervirens*, *Thymus oblongifolia*, *Rubus ursinus*, *Trillium ovatum*, *Whipplea modesta*, *Hieracium occidentale*, and *Linnaea borealis*. Succession apparently seems to be toward replacement of dominant Douglas-fir and Port-Orford-cedar by western hemlock. Hemlock seedlings and saplings are usually most abundant; seedlings of grand fir and Port-Orford-cedar are common or absent. However, sprout and vegetative reproduction of tanoak is as abundant or more so, than that of western hemlock in many stands, suggesting it may be a climax species.

Polystichum munitum dominates the understory on moister sites such as well-drained slopes or in seep areas (fig. PO-3). Greater variety of herbs and greatly reduced shrub coverage are also typical. Western Port-Orford-cedar is generally found only on these sites.

Tree regeneration is mainly western Port-Orford-cedar.

There are some areas of shallow rocky soil, where the communities are dominated by tanoak and Pacific madrone 50- to 75-cm. (20- to 30-in.) d.b.h. The understory is very dense, with 100-percent canopy coverage of low shrubs and herbs — *Rhododendron macro-*

phyllum stands on the serpentinite are more open, composed of smaller trees, western hemlock and little grand fir, and include a large variety of herbaceous species (fig. PO-3). A community dominated by Douglas-fir, Port-Orford-cedar, Camano laurel, and *Xerophyllum tenax* is typical of some serpentines; *Erythronium* and *Hieracium occidentale*, *Synthyris repens*, *Rhododendron occidentale*, *Senecio baccatus*, *Iris innominata*, and *Berberis piperifolia* are typical associates. On the dry serpentinite nose above the confluence of Johnson Creek and the Coquille River, the vegetation is a mosaic of trees, dense shrub thickets, and grassy openings (fig. PO-3). Dominant western white pine, and Port-Orford-cedar are the major trees interspersed with shrubs of *Rhamnus californica* var. *occidentalis*, *Rhododendron occidentale*, and Camano oak (*Quercus chrysolepis*). The grassy openings are rich in species such as *Subuliflora*, *Cheilanthes siliquosa*, *Campanula*, *Zigadenus fremontii*, *Coronaria*, *Calochortus tolmei*, *C. pruinosus*, *Achillea millefolium*, *Eriogonum concinnum*, *Polystichum lonchitis*, *Lithospermum* sp., and *Sedum spathulifolium*.

There are a number of wet benches and swales within the natural area (fig. PO-4). Red alder, Oregon ash, and bigleaf maple typify these areas as well as dense sedge *Carex obnupta*, *C. amplifolia*, and Cyperaceae.

Mammals believed to utilize the natural area as residents or transients are listed in table PO-1. Roosevelt elk frequent the area during the fall, winter, and spring. The natural area also provides a rich variety of habitats for amphibians. Among the species occurring here are the Del Norte salamander (*Plethodon elongatus*), Dunn's salamander

granulosa), and the Pacific treefrog (*Hyla*).

Of the specialized habitats present in the Port-Orford Cedar Research Natural Area, we have already been mentioned. These include lithosolic tanoak-Pacific madrone, serpentine, and swales. There is a small, shallow pond (several acres in area) which appears to have been formed by a slump northwest of the center of the area (section 35).

TYPE OF DISTURBANCE

There is evidence in fire scars on old-growth fir and Port-Orford-cedar that ground fires have burned through the area periodically. None appears to have occurred in recent years. The introduced root pathogen, *Phytophthora lateralis*, has not yet invaded the natural area to any substantial degree in contrast to the situation in the nearby Coquille Falls Research Natural Area. This pathogen, which is invariably fatal to Port-Orford-cedar, has apparently killed only a few trees at the edge of the natural area — near the South Fork of the Coquille River at the head of Jim Hayes Creek. More damage can be expected in the future.

The disturbance of the area is minimal. There are remains of mine workings along Jim Hayes Creek on the north edge of the natural area. Approximately 3 ha. (7 acres) of the western edge of the natural area was recently clearcut when adjacent tracts were logged about 15 years ago.

RESEARCH

There are no research studies in progress in the Port-Orford Cedar Research Natural Area. Some data on community structure and plant collections have been obtained

by Forest Service personnel.

This natural area is especially rich in research opportunities. These include studies of (1) community composition, structure and dynamics, and soil development on widely varying parent materials, and (2) the fauna and flora of an isolated pond. The possibility of eventual invasion of the area by *Phytophthora lateralis* makes community studies especially timely. The large number of southern Californian species, especially on serpentine, makes the area of special interest to the taxonomist or plant geographer.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography* — 15' Powers Agness, Oregon, quadrangles, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *geology* — *Description of the Port-Orford Quadrangle*, scale 1:250,000 (Diller 1955); *Geologic Map of the Powers Quadrangle, Oregon*, scale 1:62,500 (Baldwin and Hickey 1971); *Preliminary Geologic Map of Southern Oregon*, scale 1:250,000 (Wheeler 1955); and *Geologic Map of Oregon West of the 121st Meridian*, scale 1:500,000 (Hickey 1961). Either the District Ranger (Port-Orford Ranger District) or Forest Supervisor (Siskiyou National Forest, Grants Pass, Oregon) can provide details on the most recent aerial photo coverage and forest type maps for the natural area.

Forest type and topographic maps (scale 3 in. = 1 mi., 50-ft. contour interval) prepared by Forest Service personnel in 1938 are on file at the Pacific Northwest Forest Research Range Experiment Station, Portland, Oregon, as are records of a 1938 cruise of the natural area.

F

PRINGLE FALLS RESEARCH NATURAL AREA¹

A two-unit natural area containing ponderosa pine/bitterbrush and lodgepole pine/bitterbrush communities typical of the northern Mount Mazama pumice area in south-central Oregon.

The Pringle Falls Research Natural Area was established June 1936, to exemplify the topographically related mosaic of lodgepole pine (*Pinus contorta*) and ponderosa pine (*Pinus ponderosa*) forests characteristic of a large area of aerially-deposited Mount Mazama (Crater Lake) pumice in south-central Oregon. The 470-ha. (1,160-acre) tract is located in Deschutes County, Oregon, and is administered by the Bend Ranger District (Bend, Oregon), Deschutes National Forest. It is also a part of the Pringle Falls Experimental Forest, a 4,477-ha. (11,055-acre) area maintained by the Pacific Northwest Forest and Range Experiment Station for research and demonstration of management techniques in ponderosa and lodgepole pine forests (Moore et al 1954). The natural area is in two units. Unit 1, the western block, contains 227 ha. (560 acres) and includes nearly all of section T. 21 S., R. 9 E., Willamette meridian; and Unit 2, the eastern block, contains 243 ha. (600 acres) and encompasses most of section

ACCESS AND ACCOMMODATIONS

The natural area is located approximately 57 km. (35 miles) southwest of Bend, Oregon, and approximately 18 km. (11 miles) north of Lapine and is approached via U.S. Highway 97 and Forest Service roads. Detailed maps can be obtained at the Silviculture Laboratory, Bend Ranger Station in Bend. Access to the area is good in the summer, but snow may make access difficult. In general, travel to and from the natural area is quite easy. Forest roads are located around the tracts and one travels from Unit 1 in an east-west direction to Unit 2. Several old trails provide access to various segments of both units (fig. PR-1). Elevations at the northeast corner of Unit 1 can be reached via a logging road.

Public accommodations are available at Bend and Lapine; primitive camps are available at the northern end of the experimental forest and at Willamette Lake. A reservoir 5 km. (3 miles) west of the area is also available.

ENVIRONMENT

Topography and elevational range are similar on the two units of the natural area. The western block, is located on a relatively flat topography with a total elevation range from 1,310 to 1,320 m. (4,290 to 4,330 ft.). The eastern block, varies from a relatively flat to relatively steep on some slopes. Elevations range from 1,310 to 1,320 m. (4,290 to 4,330 ft.).

occupy the east unit, are basaltic cones.

modified continental climate prevails. precipitation occurs as snowfall during l, cloudy winter. Summers are warm, ly low in precipitation and largely ss. One to 3 months of drought are n. Climatic data from Wickiup Reser- eated 3 km. (2 miles) west of the tract ollows (U.S. Weather Bureau 1965):

annual temperature	5.7°C.	(42.3°F.)
January temperature	-4.2°C.	(24.5°F.)
July temperature	15.9°C.	(60.7°F.)
January minimum			
temperature	-10.6°C.	(12.8°F.)
July maximum			
temperature	26.8°C.	(80.3°F.)
annual precipitation	525 mm.	(20.7 in.)
rough August			
precipitation	58 mm.	(2.3 in.)

principal soil in the area has been ed as the Lapine series (Tarrant 1947). apine soil is loamy coarse sand, textured rived from aerially deposited dacite e. It is well drained and occupies 2- -percent slopes. The pumice varies 30 to 130 cm. (30 to 50 in.) in depth uried soil profiles. A small area in the ern half of Unit 1, which is easily ized by its grass dominated under- is covered by the Wickiup soil series. Wickiup is also a loamy coarse sand rmed in aerially deposited dacite pumice. ers from the Lapine by having a sea- y high water table. The Wickiup occurs pes of 0 to 5 percent and on pumice ts ranging from 130 to 150 cm. (50 to in depth.

Wickiup Reservoir, located 3 km. (2 miles) and to the west of the natural area, has ntly influenced the level of the water

<i>Pinus contorta</i> /Purshia	226 ha.	1
<i>tridentata</i>	(560 acres)	(40)

The distribution of community type defined by timber and ground vegetation maps prepared in 1934, is illustrated in figure PR-2. Both *Pinus ponderosa*/Purshia *tridentata* and *Pinus ponderosa*-*Pinus contorta*/Purshia *tridentata* can be assigned to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters and Küchler's (1964) Type 10, Ponderosa Pine Shrub Forest. *Pinus ponderosa*-*lambertiana*/Ceanothus *velutinus* communities could probably be assigned to SAF forest cover type 243, Ponderosa Pine-Sugar Fir, and Küchler's Type 5, Mixed Conifer Forest. *Pinus contorta*/Purshia *tridentata* stands can be categorized as SAF forest cover type 218, Lodgepole Pine; Küchler does not recognize lodgepole pine type. The natural area falls within a *Pinus ponderosa* community according to Dyrness and Youngberg (1978). The very recent, 6,600-year-old, pumice deposit has not weathered to produce mature type soils; therefore it is difficult to be impractical to assign the area to a "climax vegetation zone."

Unit 1, the western block, is completely dominated by pure or nearly pure lodgepole pine. Eighty to 90 percent of the area is characterized by lodgepole pine and shrub (*Purshia tridentata*) with a herbaceous cover composed of western needlegrass (*Stipa occidentalis*), Ross's sedge (*Scirpus*

allefolium, bottlebrush squirreltail, *Lupulatifolius*, and *Fragaria*. Youngberg and ns (1970) have described these comities, their soils, and forest productivity. it 2, the eastern block, has minor nts of pure lodgepole pine (fig. PR-2). undulating to rolling topography is ased with stands of ponderosa pine, bitush, and western needlegrass (Dyrness Youngberg 1966) (fig. PR-3). In some e, particularly on concave lower slopes, pole pine grows in association with ersona. Ponderosa pine and bitterbrush he conspicuous overstory and ground ation dominants, respectively; in addi- Ross's sedge, western needlegrass, brush squirreltail, and, at times, *Arcophylos parryana* var. *pinetorum* are nt. At higher elevations and on northerpes, sugar pine (*Pinus lambertiana*) and e fir (*Abies concolor*) become significant nts in the plant community. Associated the increase in these tree species is a ase in bitterbrush, an increase in *Arcophylos*, and occurrence of *Ceanothus inus*.

ule deer (*Odocoileus hemionus*) and y Mountain elk (*Cervus canadensis*) use area as spring-summer and fall range. r mammals believed to utilize the area sidents or transients are listed in table .

HISTORY OF DISTURBANCE

re scars on ponderosa pine indicate d fires periodically burned the area to initiation of fire control programs in (fig. PR-3); general fires are indicated 05, 1672, 1716, 1731, 1769, 1788, 1823, 1871, and 1886. Lack of dominant oldth fir in the presence of abundant fir duction further suggests most portions

light, and consequently, the vegetation considered unaltered by livestock use tends to be moderate with notice apparently not detrimental utilization bitterbrush. No other significant dist is known.

RESEARCH

Since the natural area is a part Pringle Falls Experimental Forest, deal of research has been and is be ducted on the tract. Two fenced are established in each block about 1934 p 8 ha. (20 acres) in the east unit and (acres) in the west unit from which has been excluded for about 35 ye PR-2). These plots contain permaner which have been photographed at lea The two plots in the eastern unit (and 28) are also sites where perio surements are made of forest grov mortality. Between 1938 and 1948, gross increment of ponderosa pine a 1.65 cu. m. per ha. per year (118 bd acre per year) and mortality avera cu. m. per ha. (50 bd. ft. per acre) n in a net growth of 0.95 cu. m. per ha. (68 bd. ft. per acre per year). Most n was caused by western pine barkbee (*droctonus ponderosae*). A portion natural area has also been used as a data source in studies of the epidem tree-killing insects, including the bar by the now-defunct Bureau of Ent and Plant Quarantine.

Baseline population levels of sev and mammal species are also being on both units of the Pringle Falls Natural Area.² This is part of a larg term eastern Oregon study utilizing other Research Natural Areas repr

to study: (1) biomass productivity in relation to soil and topographic factors; (2) forest succession since initiation of fire suppression practices; and (3) undisturbed forest for comparison with similar tracts on the natural forest which have been carefully managed under controlled experimental conditions. The natural area also provides a check site for studies of undisturbed forest over the range of south-central Oregon pumice plateau area: Pringle Falls, Mount Hood, Bluejay, and Metolius. The Natural Areas span the Mount Hood pumice deposits from south to north. The Pringle Falls Research Natural Area is a part of the Pringle Falls Experimental Forest which is similar in forest type and management. The possibility exists of using parts of the experimental forest for solving destructive sampling or management problems and using the natural area as a

AND AERIAL TOPOGRAPHS

Four special maps covering the natural area were prepared by Civilian Conservation Corps during the 1930's and are on file at the Pacific Northwest Forest and Range Experiment Station's headquarters in Portland. The Silviculture Laboratory in Bend, Oregon, has the maps have a scale of 1 inch equals 1 mile. Included are a topographic map with 10-foot contour interval and maps of timber types, timber size classes, tree reproduction, tree density and species, and ground cover. Data from a timber cruise of the natural

area were used by Hyman, C. F., and C. F. Youngberg.

Lower right: Stand of lodgepole pine, bitterbrush, and Idaho fescue typically found on finer textured soils.

QUINAUT RESEARCH NATURAL AREA¹

A coastal plain tract of western
hemlock, Sitka spruce, western red-
cedar, and Douglas-fir located on
the southwestern edge of the Olym-
pic Peninsula.

The Quinault Research Natural Area was
established on June 18, 1932, as an example
of Sitka spruce type in its natural state. The
area (1,468-acre) tract is located in Grays
County, Washington, and is adminis-
tered by the Quinault Ranger District (Quin-
ault National Forest, Olympic National Forest).
The natural area occupies all except 2 ha. (5
acres) of section 31 and the W½ and W½
of section 32, T. 23 N., R. 9 W., and
W½ of section 6 and W½ NW¼ of section
22 N., R. 9 W., Willamette meridian. It
is at 47°27' N. latitude and 123°52' W.
longitude.

ACCESS AND ACCOMMODATIONS

Access is via U.S. Highway 101 which
runs the west side of the Quinault Research
Natural Area (fig. QU-1) about 64 km. (40
mi.) north of Hoquiam and 1.6 km. (1 mile)
north of Amanda Park. No other roads or
trails enter the tract. Commercial accommo-
dations as well as several excellent public

ENVIRONMENT

The Quinault Research Natural Area
lies at elevations from about 122 to 366 m. (400 to 1,200
ft.) in elevation with the bulk of the area
between 122 to 152 m. (400 to 500 ft.). Topography
is generally gently rolling except along the eastern
edge where the steep lower slopes of Quinault
Ridge are encountered. Willaby and
Creeks flow through the tract, and
many of their small tributaries rise within it.

The natural area straddles the
boundary between marine terrace deposits of
Pliocene age and basalt flows and breccias
deposited during the Eocene epoch (Huntington
1961). The latter materials, belonging to the
Metchosin formation (Danner 1956), are
limited to the slope of Quinault Ridge. The
terrace deposits are covered with drift
deposited by alpine glaciers which occupy
the area three times during the Wisconsin
glaciation and at least once, pre-Wisconsinan (Carter
1964).

A maritime climate, wet with moder-
ate temperature extremes, prevails. Winters are
cool and summers are cool with frequent
foggy days. Precipitation is heavy but highly
seasonal with January and December the
wettest months. Only about 7 percent of the
annual precipitation falls during June, July,
and August, and some years a drought period
of a month or more occurs. Snow is rare. Climate
data from the nearby Quinault Ranger Dis-
trict are as follows (U.S. Weather Service
1956):

The soils on the area have not been mapped or described. They appear relatively deep and loamy with varying amounts of loose rock. At least a portion would probably be classed as Sols Bruns Acides. Soils on gentle topography are underlain by compacted glacial till.

BIOTA

Estimated areas by SAF cover types (Society of American Foresters 1954) are:

No.	Name	Area
224	Western Hemlock	314 ha. (775 acres)
225	Sitka Spruce-Western Hemlock	162 ha. (400 acres)
227	Western Redcedar-Western Hemlock	81 ha. (200 acres)
230	Douglas-Fir-Western Hemlock	24 ha. (60 acres)

The area would probably fall entirely within Küchler's (1964) Type 1, Spruce-Cedar-Hemlock Forest, and the *Picea sitchensis* Zone as defined by Franklin and Dyrness (1969).

Western hemlock (*Tsuga heterophylla*), Sitka spruce (*Picea sitchensis*), Douglas-fir (*Pseudotsuga menziesii*), and western redcedar (*Thuja plicata*) dominate the Quinault Research Natural Area. Although all four species are distributed throughout the area, there tend to be local concentrations (fig. QU-1). Sitka spruce is best represented in the central portion of the natural area but does not occur as a pure stand. Western hemlock is the most abundant species and occurs as a pure or nearly pure type (80 percent by volume) on some of the slopes along the eastern boundary. It also dominates a comparatively young stand along the western boundary. Western redcedar is most abundant in the northwestern corner of the tract.

western redcedar (fig. QU-2). 400-year-old Douglas-fir reach almost 90 m. (300 ft.) and diameters 100 cm. (70 in.) or more at b.h. Sitka spruce and western hemlocks are generally smaller, perhaps 150 to 200 years old. In the central portion of the natural area, Douglas-fir dominants are in excess of 100 years old, tall and have diameters averaging 100 cm. (35 to 40 in.) b.h. and, rarely, reaching 150 to 180 cm. (60 in.) b.h. Western Hemlocks are generally somewhat smaller. The stand of young western hemlock near the western boundary has many trees 50- to 60-cm. (20- to 24-in.) d.b.h.

Succession in the Quinault Research Natural Area is primarily toward the replacement of existing mixed forests by western hemlock. Only western hemlock is common in all age classes. Seedlings of hemlock are abundant in the forest openings are completely closed by western hemlocks (fig. QU-2). Reproduction of western redcedar and Douglas-fir is almost entirely absent. Small Sitka spruce is common, especially on rotten logs. Spruces are not so abundant as those of hemlock. Sapling spruce are rarely found. In open, wet depressions dominated by old western redcedar and Sitka spruce, saplings provide a possible successional pathway. Saplings are almost as abundant in these areas as those of hemlock. On the Ridge, Pacific silver fir is restricted to closed forests and will appear in the climax forest.

Most tree reproduction is in the "nurse logs," which are hundreds of hemlock and Douglas-fir (fig. QU-2). Some of these saplings roots reach mineral soil. The roots are visible throughout the

Maianthemum bifolium var. *kamschaticum*, *Blechnum spicant*, *Galium triflorum*, *Viola sempervirens* are less common. Depressions or swampy areas differ considerably. Species there include *Rubus speciosus*, vine maple (*Acer circinatum*), *Viola* sp., *Trillium ovatum*, *Cardamine* sp., *Ranunculus aparine*, *Rhamnus purshiana*, and *Cyperaceae*.

The natural area lies within the so-called "rain forest" region of the western Olympic Peninsula, mosses and liverworts on the ground, down logs, shrubs, and stumps. Some of the more common ground plants are *Eurhynchium oreganum*, *Hypnum* sp., *Rhytidiadelphus loreus*, *Mnium* sp., *Hylocomium splendens*, and *Moss* sp. Among the abundant epiphytes are *Isotrichum stoloniferum*, *Porella navicularis*, *Rhytidiadelphus loreus*, *Radula* sp., *Frullania nisqualensis*, *Scapania* sp., and *Ptilidium californicum*.

Roosevelt elk (*Cervus canadensis roosevelti*) is the most important animal present. The natural area as a wintering place. The relatively open, parklike nature of the tract is a consequence of their activity; their trails ease the problems of travel through the area. Undoubtedly, they have also affected the composition of the forest vegetation (Sharpe 1956). Other animals believed to utilize the area as residents or transients are listed in table 1.

Invertebrates recorded by Shelford (1963) during a visit in 1945 included: millipedes (*Parasphinctus haydeniana*), centipedes (*Archiscolopagus melanonotus* and *Otocryptops* sp.), spiders (*Hexura picea* and *Antrodiaetus* sp.), numerous brown silverfish, camel crickets (*Pristocentrophilus* sp.), ground

squirrels, lakes, ponds, rock outcrops, etc., exist within the natural area.

HISTORY OF DISTURBANCE

There is evidence that fires burned over the area 200 or more years ago. So many scars can be seen on old western redwood and Douglas-fir. There is no indication of more recent fires.

Human disturbance prior to establishment of the natural area is believed to have had a minor influence on natural conditions. One time an old pioneer road ran through the area near the base of Quinault Ridge. During World War I the Spruce Production Division built two short skidways into Section D. They took out a few spruce trees. Finally, dead cedar was utilized for fence posts.

There has been no disturbance since establishment except for that associated with maintenance of U.S. Highway 101.

RESEARCH

A number of scientists have visited the area in connection with zoologic, geographic, botanic, and paleological studies of the Olympic Peninsula but generally have not published their observations with specific reference to the natural area. One exception is Dr. Victor E. Shelford whose observations on invertebrate fauna (Shelford 1963) were made earlier. The natural area has been visited as part of two studies currently being made on temperate forest communities on the Olympic Peninsula.²

Special research opportunities which exist on the Quinault Research Natural Area include possibilities for studying (1) the effects of Roosevelt elk on their habitat and (2) ecology of epiphytic mosses and lichens

area include: *Topography* — 15' Quinault Lake, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *geology* — *Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). Either the District Ranger (Quinault Ranger District) or Forest Supervisor (Olympic National Forest, Olympia, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

Records of the 1931 timber inventory and copies of the original forest type and topographic maps, prepared by Forest Service personnel, are on file at the Pacific Northwest Forest and Range Experiment Station, Portland, Oregon.

RAINBOW CREEK RESEARCH NATURAL AREA¹

virgin grand fir-western white pine,
Douglas-fir - ponderosa pine and
western larch stands typical of the
interior mixed-conifer forest zone in
the northern Blue Mountains of
southeastern Washington.

Rainbow Creek Research Natural Area
established November 6, 1968. It ex-
cludes three forest types which are eco-
logically and commercially important in the
northern Blue Mountains of northeastern
Oregon and southeastern Washington. The
area (420-acre) tract is located in Columbia
River, Washington, and is administered by
Pomeroy Ranger District (Pomeroy,
Washington), Umatilla National Forest. Un-
derstandably, topographic boundaries give it an
irregular shape (fig. RC-1). It occupies por-
tions of sections 14, 22, 23, and 26, T. 7 N.,
E., Willamette meridian. It lies at 45°
N. latitude and 117°50' W. longitude.

ACCESS AND ACCOMMODATIONS

Access is rather difficult because the nearest
road terminates approximately 3 km. (2 miles)
from the tract at Godman Guard Station.

Motor traffic is prohibited on the trail.
Regional Forester because the Rainbow
Creek Research Natural Area lies entirely within
designated Wanaha Back-Country Area.
Public accommodations are available in
Walla Walla, Washington, about 40 km. (25 miles)
west. Primitive camps are located along
Skyline Road, and there is a developed
campground at Godman Guard Station.

ENVIRONMENT

The Rainbow Creek Research Natural
Area varies from 1,100 m. (3,600 ft.) to a maximum
of 1,440 m. (4,700 ft.) in elevation to the
summit of Sugarloaf Butte. The topography
varies from rolling to steep on the slopes of
the butte and all aspects are preserved (figs.
RC-1 and RC-2).

The natural area is on an uplifted
plateau of Columbia basalt flows with some
ash deposits in the forested areas. Sugarloaf
Butte represents a residual island on a
deeply eroded and dissected area.

A modified continental climate prevails
with cool, moist, partly cloudy winters and
warm, dry, cloudless summers. Precipitation
is moderate and seasonal, usually occurring
as snow. The nearest climatic station (Walla
Walla, Washington) is 32 km. (20 miles)
west of the tract on the Columbia River
plateau and outside of the topographic area.
modified climate; data from this station are
as follows (U.S. Weather Bureau 1965).

the Umatilla and shallow, stony Umatilla categories (Washington State Agricultural Experiment Station 1954). They may be broadly classed as Gray Wooded. Shrub and grassland soils tend to be shallow, stony Lithosols with little to moderate profile development. These soils are located on upper portions of the butte, on ridge tops, and on steeper, colluvial areas.

BIOTA

Estimated areas by cover type are:

Name	Area
Grand fir-western white pine	57 ha. (140 acres)
Douglas-fir-ponderosa pine	93 ha. (230 acres)
Western larch	16 ha. (40 acres)
Grass and shrubs	4 ha. (10 acres)

The primary forest types of interest are the grand fir (*Abies grandis*) and western white pine (*Pinus monticola*) stands which are probably assignable to SAF forest cover type 213, Grand Fir-Larch-Douglas-Fir (Society of American Foresters 1954), and Küchler's (1964) Type 14, Grand Fir-Douglas Fir Forest. The Douglas-fir (*Pseudotsuga menziesii*) and ponderosa pine (*Pinus ponderosa*) forests form an intricate intergrading mosaic and probably best fit SAF type 214, Ponderosa Pine-Larch-Douglas-Fir, or Küchler's Type 11, Western Ponderosa Forest, and Type 12, Douglas Fir Forest. The western larch (*Larix occidentalis*) stand is assignable to SAF type 212, Larch-Douglas-Fir, and is what Küchler considers seral to his Type 14, Grand Fir-Douglas Fir Forest. Grasslands are dominated by wheatgrasses (*Agropyron* spp.) and fall in Küchler's Type 51, Wheatgrass-Bluegrass. The entire area lies within the *Abies grandis* Zone of the Blue Mountains (Franklin and Dyrness 1969).

The grand fir-western white pine type

and western larch account for most of the vegetation is dominated by *branaeum*, along with *brevifolia*), thinleaf alder (*Alnus*), *Rosa* spp., and 10 to 15 species of grasses. Tree reproduction is entirely of grand fir; shrub reproduction is nearly all of Douglas-fir.

The Douglas-fir-ponderosa pine forest occurs primarily on the south-facing slopes of Sugarloaf (fig. RC-1) and is associated with small areas of shrub communities. The stand of western larch (fig. RC-2) occurs on the north and represents natural regeneration following catastrophic fires.

Rocky Mountain elk (*Cervus elaphus*) use the area extensively for winter range. The animals usually range from Sugarloaf Creek to winter along the south-facing slopes. Grass utilization by elk has decreased since some change in the grass cover, and may be influenced by the Pacific yew within the forest. The mammals believed to utilize the area are deer or transients are

HISTORY OF DISTURBANCE

Occasional fire-blackened stands of western larch stand indicate the effects of catastrophic fires.

Domestic livestock, primarily cattle, grazed the tract to some extent from about 1945 when they were removed. In the past 20 to 30 years, elk have increased significantly and are altering some aspects of the forest communities.

Recreation use is rather limited. Grazing from pastures might have some influence on the

ARCH

research is known on the area. The natural area provides interesting opportunities for study: (1) effect of slope aspect on vegetation; (2) soil-vegetation relationships and factors responsible for the mosaic pattern of forest and nonforest communities; (3) natural successional relationships of both western white pine and western larch; and (4) biomass production as affected by soils and topography within a single macroclimate.

S AND AERIAL TOGRAPHS

Special topographic or geologic maps are not available for the natural area which are sufficiently detailed to be useful. Either the District Ranger (Pomeroy Ranger District) or Forest Supervisor (Umatilla National Forest, Pendleton, Oregon) can provide details of the most recent aerial photo coverage of the area.

LEGEND

BOUNDARY, RAINBOW CREEK RESEARCH NATURAL AREA

Figure RC-2.—Natural features of the Rainbow Creek Research Natural Area. Upper left: Aerial view of Sugarloaf Butte showing the southerly slope which has western white pine in the draws and on the lower slope (the two bottom photographs were taken in this area). Upper right: Aerial view of the northwest slope showing the stand of western larch and some bunchgrass openings. Lower left: Stand of grand fir and western white pine with some Douglas-fir on lower slope position; Pacific yew, *Vaccinium membranaceum*, *Rosa* spp., and forbs dominate the understory. Lower right: One of the largest western white pines; note clumped branches on the Pacific yew behind the pine caused by heavy browsing of elk in winter.

RATTLESNAKE HILLS RESEARCH NATURAL AREA^{1 2}

Shrub-steppe vegetation (e.g., big
agebrush communities) in the arid
interior of southeastern Washington.

The Rattlesnake Hills Research Natural
Area was established to provide examples of
shrub-steppe communities characteristic
of most arid portions of the Pacific North-
west. It is an island of natural vegetation
surrounded by expanses of cultivated fields
and dryland or irrigated management
practices. The 33,350-ha. (75,000-acre) tract
is located within the boundaries of the U.S.
Atomic Energy Commission's Hanford Works
Reservation in Benton County, Washington.
Research on the tract is managed for the
Atomic Energy Commission by the Battelle
Memorial Institute, Pacific Northwest Labo-
ratories, Richland, Washington. The eastern
boundary of the natural area is formed by
Highway 240, while the western bound-
ary follows the natural skyline of the Rattle-
snake Hills (fig. RH-1). It is located at 46°30'
latitude and 119°40' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is most easily reached via
Highway 240 from Richland which is

traffic is restricted to existing roads;
travel by vehicles is prohibited. Sever
are paved; to provide all-weather a
most of the natural area, some of th
troublesome unimproved routes hav
stabilized with river gravel and crush

It is necessary to obtain permission
to enter the tract from the Pacific Northwest
Laboratories' Arid Lands Ecology Project
Office, Atomic Energy Commission's Richlan
Operations Office. Inquiries for permission
to enter the reserve should be directed to Dr.
E. Vaughn, Manager, Ecosystems
Management, Battelle-Northwest, Richland,
Washington 99352. There are no restrict
on photography within the natural area.
Firearms are not allowed unless ne
to perform research.

There are no living accommodation
within the natural area, but numerous facilit
are available in the nearby cities of R
Pasco, Kennewick, and Benton City.

ENVIRONMENT

The Rattlesnake Hills Research
Area occupies the northeasterly facing
of the Rattlesnake Hills, the south
extremity of Yakima Ridge, and inte
gentle slopes and valleys. Elevation
from 150 m. (500 ft.) on the valley
1,060 m. (3,500 ft.) along the crest
of the Rattlesnake Hills. The tract is unde
layers of Columbia River basalt of
age but these are covered by eolian a
vial materials of variable thickness (H

altitude 46°34' N., longitude 119°35' W., elevation 224 m. or 733 ft.). Data collected at this station are available as monthly summaries and include daily values for air temperature, precipitation, wind speed and direction, relative humidity, and solar radiation. Some average values are as follows:

mean annual temperature11.7°C. (53.1°F.)
mean January temperature-1.3°C. (29.6°F.)
mean July temperature20.4°C. (68.8°F.)
mean January minimum temperature-10.2°C. (13.7°F.)
mean July maximum temperature33.3°C. (91.7°F.)
average annual precipitation	...171.2 mm. (6.74 in.)
average annual snowfall32.0 cm. (12.6 in.)

Although the meteorological station yields relevant data, it is not representative of the climate of the entire natural area. A series of 25 stations have been located throughout the tract and since 1969 have provided data on precipitation and maximum and minimum air temperature (Hinds and Thorp 1959). These data are also available as monthly summaries. An automated microclimatological station has recently been established at 666-m. (1,200-ft.) elevation within the Grassland and Biome study area.

Soils within the natural area have been mapped (Hajek 1966). Based on acreage, the Warden and Ritzville silt loams occupy most of the land area; they are found on the lower and middle slopes of the Rattlesnake Hills. Steep slopes, ridge crests, draw bottoms, and alluvial fans are mapped as Lickskillet, Kiona, and Scootene silt loams. The basal plains are mapped as Esquatzel silt loam, Ephrata stony loam, Burbank sandy loam, and Hezel and Koehler sand. These series are classified by great soil group and according to the 7th Approximation in table RH-1.

The **Ritzville silt loam** series consist of dark colored soils midway up the slopes of

surface. The **Warden silt loam** series is found on the lower slopes of the Rattlesnake Hills and adjoin Ritzville soils at elevations above 360 m. (1,200 ft.). The surface 2 dm. is grayish brown in color (10 YR 4/2). The subsoil is strongly calcareous at a depth of 15 cm. The soil is usually more than 15 cm. thick. The **Kiona silt loams** are associated with the Warden and Ritzville soils and occupy stony slopes and ridges. The surface soil is grayish brown (10 YR 3/2) and is usually 15 cm. thick. The dark brown (10 YR 4/2) subsoil contains large basalt fragments, some larger in diameter. **Lickskillet** soils occupy ridge tops above 765-m. elevation in the Rattlesnake Hills. These soils are shallow over basalt bedrock. Fragments of basalt present throughout the soil profile. This series is similar to the Scootene series except that the surface soils are very dark brown (10 YR 2/2). The **Scootene silt loams** are formed in recent alluvium. The color and texture of the subsoil indicate the stratified nature of the alluvium. **Esquatzel** soils are associated with the Warden and Ritzville soils and often seen on developed from sediments eroded from the Rattlesnake Hills. These soils are in two series. **Scootene stony silt loam** is found on the northerly-facing slopes of the Rattlesnake Hills and are usually found to the bottoms of narrow draws. These areas are shaped where draws empty into the adjoining plain. These soils are severely eroded with numerous fragments of basalt. The surface soil is usually dark grayish brown (10 YR 4/2). **Ephrata sandy loam** is associated with the Burbank soil. The surface soil is very dark grayish brown (10 YR 3/2), and the subsoil is dark grayish brown (10 YR 4/2). The medium textured soil is underlain by gravelly material.

Hezel sands have developed under *Artemisia* and *Grayia* in coarse sandy alluvial fans. Relief characteristically consists of rocky terraces and dunelike ridges. The surface soil, which is approximately 9 dm. thick, is very dark brown (10 YR 3/3) and was probably formed in wind-blown sand which covered finer textured lacustrine sediments. Subsoil is a dark grayish brown (10 YR 4/2) sandy loam. **Koehler sands** are similar to the Hezel sandy soils but differ in that they lack the lime and silica cemented "pan" layer. The surface soil is very dark grayish brown (10 YR 3/2) and the silty subsoil (10 YR 4/2) is encountered at about 5 dm.

Chemical characterizations of soils and sediments have been published (Wildung and Hajek 1969, Wildung, Hajek, and Price 1970). Selected data for the Ritzville and Hezel series are provided in table RH-2.

TA

Vegetation. — The Rattlesnake Hills Regional Natural Area was selected as a natural area primarily because of the presence of undisturbed stands of several typical shrub steppe communities, although the vegetation also includes some disturbed plant communities. Of particular interest are the stands representative of the *Artemisia tridentata*/*Agropyron spicatum*, *Artemisia tridentata*/*Poa secunda*, and *Eriogonum thyrsiflorum*/*Poa secunda* Associations described by Daubenmire (1970). However, some rare and ecologically significant associations are not present such as the *Eurotia lanata*/*Poa secunda* type (Daubenmire 1970). Undisturbed or even lightly disturbed examples of various shrub steppe communities found in the natural area are extremely difficult to find elsewhere. Some of the communities in-

found in eastern Washington (Daubenmire 1970).

The *Artemisia tridentata*/*Agropyron spicatum* Association (fig. RH-2) occurs at elevations generally above 300 m. (1,000 ft.) in the *Artemisia tridentata*/*Poa secunda* Association occurs below this elevation on slopes and on the plain. Both kinds of association are subject to fire damage. Wildfires burn through a stand of the *Artemisia tridentata*/*Agropyron* or *Artemisia*/*Poa* Association. The shrubs are effectively killed but the perennial grasses survive. There are a number of stands dominated exclusively by bunchgrass which have been created in this way; they gradually reinvade these areas. Under increasing stress, the perennial grasses are reduced, and invasion by alien winter annuals, especially cheatgrass brome (*Bromus tectorum*) is prevalent (fig. RH-2).

The *Artemisia tridentata*/*Agropyron spicatum* Association is dominated by big sagebrush (*Artemisia tridentata*) and blue bunch wheatgrass (*Agropyron spicatum*). *Grayia spinosa* is sometimes present in a shrub layer along with the low shrubs *Eriogonum filifolium* and *Phlox longifolia*. Big sagebrush coverage varies from 5 to 26 percent in this association (Daubenmire 1970). Blue bunch wheatgrass is the major perennial grass with a typical coverage value of 50 percent. Sandberg bluegrass (*Poa secunda*) is always present with around 30 percent cover. Small amounts of *Stipa comata* and *Poa cusickii* are also typical. Annuals present include cheatgrass brome, *Bromus tectorum*, *F. pacifica*, *Descurainia filifolia*, and *Draba verna*.

The *Artemisia tridentata*/*Poa secunda* Association lacks any large grasses and has a higher density of big sagebrush (Daubenmire 1970). Big sagebrush coverage is typi-

ron Association have (15 to 20 indigenous) (Daubenmire 1970).

Along the ridge crests that form the main mass of the Rattlesnake Hills, basalt outcrops support vegetation characteristic of the *Eriogonum thymoides*/*Poa secunda* Association (fig. RH-2). Here low growing plants of *Eriogonum thymoides*, *Phlox hoodii*, *Haplopappus stenophyllus*, and *Balsamorhiza rosea* and Sandberg bluegrass grow widely spaced as clumps rooted in the rock crevices. Figure RH-2 includes a closeup photograph of *Lewisia rediviva*, one of the plants found in these lithosolic habitats. At the crest of the Rattlesnake Hills snow accumulates in deep drifts on the eastern slopes as it is transported by strong westerly winds. The melting snow provides soil moisture which is exploited by plants not found elsewhere on the reserve. Especially conspicuous are *Lupinus* spp. (fig. RH-2) and a perennial bunchgrass, Idaho fescue (*Festuca idahoensis*).

Permanent springs are scarce on the reserve. Two of the most copious are located at Rattlesnake Springs and in Snively Gulch. The extent of the riparian vegetation in Snively Gulch is illustrated in fig. RH-2. The important species are black cottonwood (*Populus trichocarpa*), *Salix exigua*, as well as other *Salix* species, *Prunus americana*, *Rhus glabra*, and *Philadelphus lewisii*. Although riparian communities occupy only a few acres, they are an extremely important nesting habitat for birds. The springs also provide drinking water for numerous birds and mammals and support an aquatic fauna.

Although big sagebrush and, sometimes, hopsage are the common shrub dominants over most of the natural area, there are several thousand acres on the lower slopes of the Rattlesnake Hills occupied by winterfat- (*Eurotia lanata*) dominated communities (fig. RH-2). The 2 communities are

In the past, plant ecology of Rattlesnake Hills Research Natural Area centered around the mineral relationships of halophytes (Rickard 1965, Rickard 1965a, Rickard 1967b, and Rickard and Keo 1967). The influence of microclimate on winter annuals (Hinds and Rickard, Hinds, and Gilbert 1967) and composition of the plant community (Daubenmire 1970). Radionuclides have been useful in obtaining data on the distribution of big sagebrush (Price 1970).

Current studies in plant ecology are concerned with measuring primary production of winter annuals on abandoned fields at different elevations and the climatic and edaphic variables affecting soil moisture, temperature, and nutrient levels. Estimates of aboveground production have been made over the past several years. The results of harvests of two old fields at different elevations of the natural area. The peak yield in 1971 are shown in table 1 and are expressed as grams of oven-dried material per square meter of ground = 1000 ± error of the mean for total material.

Taxa

Taxa	1969	1970
<i>Bromus tectorum</i>	300	1
<i>Poa secunda</i>	(1,000)	
<i>Sisymbrium altissimum</i>		
<i>Amsinckia lycopsoides</i>		
<i>Descurainia pinnata</i>		
<i>Tragopogon dubius</i>		
<i>Microseris laciniata</i>		
<i>Holostemum umbellatum</i>		

Total live material 211

The dominant plant on both sites was cheatgrass — 94 and 88 percent of the production on the low elevations.

been measured at less than 100 g/m².

fauna. — The game animals characteristic of the natural area are the mule deer (*Odocoileus hemionus*), cottontail rabbit (*Sylvilagus nuttallii*), chukar (*Alectoris gracea*), red-necked pheasant (*Phasianus colchicus*), quail grouse (*Centrocercus urophasianus*), California quail (*Lophortyx californicus*), and mourning dove (*Zenaidura macroura*). Only chukar and dove exist in populations of sufficient size to support even limited hunting with a rifle.

The fur-bearing animals are the coyote (*Canis latrans*), badger (*Taxidea taxus*), and bobcat (*Lynx rufus*). The population levels of these animals are unknown but badgers are probably more scarce than coyotes; the bobcat is rarely seen on the natural area.

The most abundant small mammal in the reserve is the Great Basin pocket mouse (*Perognathus parvus*) (fig. RH-2). This mammal has been intensively studied by Dr. T. P. Marshall by mark-recapture technique in several vegetation types on the natural area. A study of the distribution of small mammals in relation to the elevational gradient in the Rattlesnake Hills has been carried out by Rickard (1970). Other small mammals that occur on the project are deer mouse (*Peromyscus maniculatus*), northern grasshopper mouse (*Onychomys leucogaster*), western harvest mouse (*Reithrodontomys megalotis*), Townsend ground squirrel (*Citellus townsendii*), vagrant shrew (*Sorex vagrans*), sagebrush vole (*Lagurus curtatus*), and northern pocket gopher (*Thomomys talpoides*). Black-tailed jackrabbits (*Lepus californicus*) occur on the natural area but mostly at low elevations, and the least chipmunk (*Eutamias amoenus*) occurs only at high elevations.

The most abundant breeding birds in steppe vegetation at low elevations are the horned

breeding birds. Many birds are migratory and utilize the reserve for resting and nesting stops. This is particularly true of the horned crowns (Zonotrichia leucurus), crowned sparrows (Zonotrichia leucurus), and warblers (Parulidae), and vireos (Vireonidae).

The riparian tree-shrub community provides breeding sites for the black-billed cuckoo (*Coccyus erythrophthalmus*), western and eastern bluebirds (*Sialia mexicana* and *Sialia sialis*), western tanager (*Tyrannus verticalis* and *T. tyrannus*), western bunting (*Passerina amoena*), red-breasted flicker (*Colaptes cafer*), and starling (*Vulgaris*). Killdeer (*Charadrius urophasianus*) and long-billed curlew (*Numenius americanus*) nests have been found in the vernal pools at Rattlesnake Springs. A survey of bird populations in riparian plant communities has been reported for the Yakima River valley near Richland (Rickard 1964).

Birds of prey nest on the natural area, especially the sparrow hawk (*Falco sparverius*), Swainson's hawk (*Buteo swainsoni*), northern horned owl (*Bubo virginianus*), marsh owl (*Circus cyaneus*), and burrowing owl (*Scotopelia cunicularia*). The golden eagle (*Haliaeetus chrysaetos*) is a frequent winter visitor.

Little is known about the dynamics of the populations of reptiles on the natural area. Some information is available concerning the altitudinal distribution of the side-blotched lizard (*Uta stansburiana*) (Rickard 1970) as well as the time of onset of winter dormancy (Rickard 1967). Other reptiles observed on the natural area are the Pacific rattlesnake (*Crotalus viridis*), gopher snake (*Idem melanoleucus*), yellow-bellied racer (*Coluber constrictor*), and the short-horned lizard (*Phrynosoma douglassi*).

The invertebrate fauna of the natural area has received little attention. A taxonomic survey of foliage dwelling insects is currently under way for several years by Dr. J. L. Cone of Washington State University.

abundant and these insects provide a substantial part of the coyote diet during the few weeks the beetles are active on the soil surface. During one especially favorable season, autumn emergent beetles were estimated to provide 20 kg. of live biomass per hectare.

HISTORY OF DISTURBANCE

The grazing history of the natural area prior to 1943 is not documented. However, local ranchers recall sheep and cattle grazing in the Rattlesnake Hills prior to that time. No grazing has been allowed since 1943, and the area is now fenced in its entirety to exclude wandering livestock. The condition of the various plant communities and abundance of several highly palatable forage plants such as winterfat (*Eurotia*) and hopsage (*Gutierrezia*) suggest that whatever grazing took place has probably been a minor disturbing influence. Water was probably a seriously limiting factor in utilization of the tract by domestic stock.

Some portions of the natural area were also farmed prior to Federal acquisition of the tract in 1943. The communities on these abandoned fields are undergoing natural succession and are being utilized in comparative studies with the natural vegetation.

Most recent human disturbance has resulted from off road military vehicle use during war games in 1965. These left numerous track scars on part of the landscape. Under present management, human disturbance is minimal and existing roadways are improved in lieu of new road construction.

Fire has been and continues to be an important natural disturbance. An extensive wildfire occurred in the summer of 1957 and

technicians of the Battelle students and faculty from Washington, Washington (Oregon State University, Idaho are utilizing the tract (40 acres) of the natural area designated and under study Lands Ecology) coordinating national Biological Program Biome project.

Much of the ongoing research cited earlier in this description of the area; included is research in micrometeorology, plant ecology and synecology), hydrology, and soil science studies involve: productivity relationships of plants in abandoned fields and in pristine plant studies of small mammal populations various plant community management as treatment with selective addition of moisture using trickle irrigation; and hydrological nutrient relationships in the community.

Research facilities are three laboratory sites on the tract. These are: a small 20-building located at Rattlesnake building complex located at the level at the southern edge and another building complex of the Rattlesnake Hills. Southern edge of the reservation facilities are primarily utilized for research, and the last named facility.

RATTLESNAKE HILLS RESEARCH NATURAL AREA

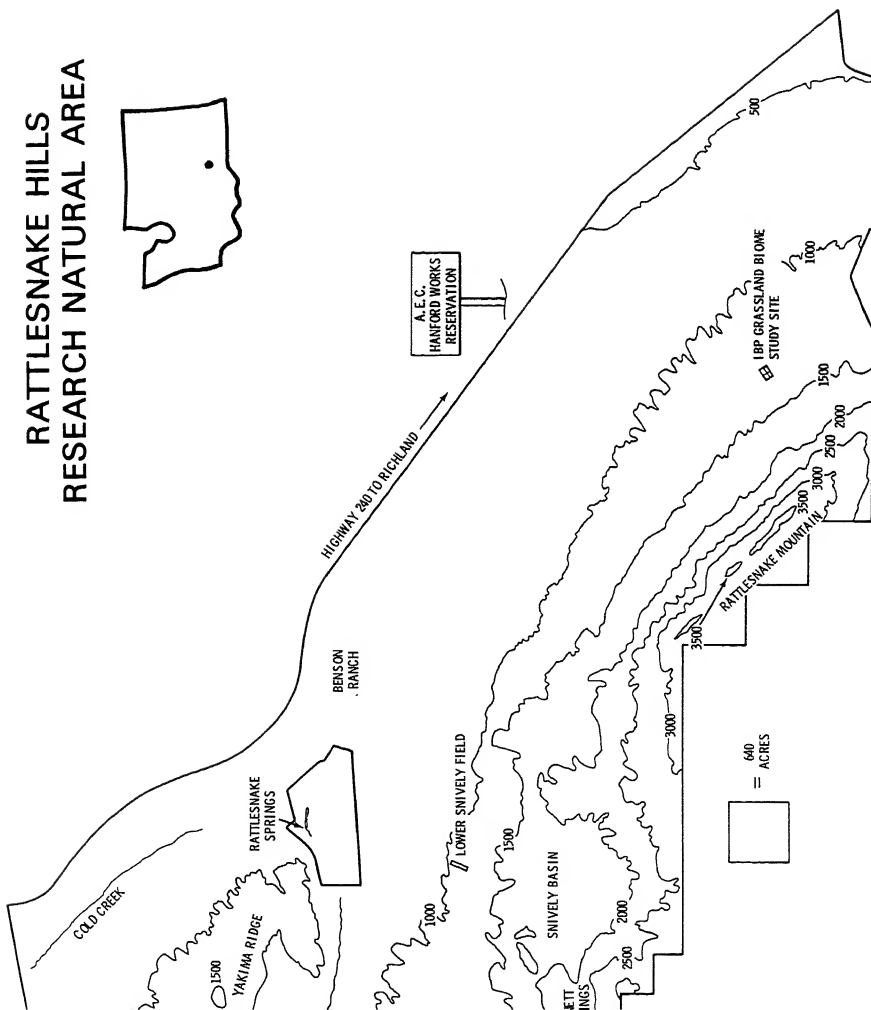

Figure RH-2.—Natural features of Rattlesnake Hills Research Natural Area. (All photos courtesy of Dr. T. P. O’Farrell, Battelle Northwest.) A: Pristine community representative of the *Artemisia tridentata*/*Agropyron spicatum* Association which is typical of higher elevations; note the Rattlesnake Hills in the background. B: Community dominated by big sagebrush and hopsage typical of those found on the basal plain; the understory is composed of cheatgrass brome, an alien annual grass which is highly successful on habitats disturbed by grazing.

Figure RH-2.—Natural features of Rattlesnake Hills Research Natural Area (continued). C: Winterfat forms islandlike stands which are surrounded by communities of big sagebrush on the lower slopes of the Rattlesnake Hills. D: The most extensive stand of deciduous shrubs and trees which is found along a spring-fed brook below Snively Basin.

Figure RH-2.—Natural features of Rattlesnake Hills Research Natural Area (continued). E: Lithosolic communities inhabit stony outcrops in the Rattlesnake Hills; typical species illustrated here are *Balsamorhiza rosea* and Sandberg bluegrass. F: *Lewisia rediviva*, another conspicuous plant on lithosolic sites in the Rattlesnake Hills. G: *Lupinus* providing a conspicuous display of color following snow melt; snowdrifts persist late into the spring on northeast-facing slopes at the crest of the Rattlesnake Hills. H: The most abundant mammal on the natural area, the Great Basin pocket mouse (*Perognathus parvus*).

H

SISTER ROCKS RESEARCH NATURAL AREA¹

Pacific silver fir stands on a mountain ridgetop of Eocene-Oligocene volcanics in the Washington Cascade Range.

Sister Rocks Research Natural Area was established on September 5, 1967. It preserves Pacific silver fir (*Abies amabilis*) as they occur on mountain slopes and ridgetops in older (Eocene-Oligocene) volcanic portions of the Cascade Range. The 87-15-acre tract is located in Skamania County, Washington, and is administered by the Wind River Ranger District (Carson, Washington), Gifford Pinchot National Forest. The tract occupies portions of sections 10, and 11, T. 5 N., R. 6 E., Willamette Meridian (fig. SR-1), based upon natural boundaries and locations of Roads N63 (on the south) and N63J (proposed, on the north). It is at 45°56' N. latitude and 122°03' W. longitude.

ACCESS AND ACCOMMODATIONS

Access to the vicinity is easiest from the north via the Columbia River (U.S. Highway 30), Carson, and the Wind River valley (Forest Roads 30, N73, N64, and N63); it can

(fig. SR-1). The trail provides access to the central and southern portions of the tract. Bounding roads (existing and planned) are shown on the remainder. At present, eastern portions are least accessible.

The nearest commercial accommodations are in Stevenson, Washington, about 25 miles away, or occasionally, in Carson. However, there are several improved camps in the adjacent Wind River valley.

ENVIRONMENT

The Sister Rocks Research Natural Area occupies a broad, north-trending ridge. Slopes are generally gentle to moderate (10- to 30-percent) except along the lower margins of the area where steeper (60- to 80-percent) slopes occur. Elevations range from 1,100 to 1,280 m. (3,600 to 4,200 ft.).

Geologically, the natural area is underlain by Eocene-Oligocene volcanics. Underlying bedrock is composed of Eocene-Oligocene volcanics, predominantly andesite in character (Huntington et al. 1961). Within the overburden are elements of Pleistocene and/or Recent volcanic activity, including pumice falls, some of the ejecta from which form distinct layers.

The climate is wet and cold. Precipitation is seasonal, peaking during winter months and reaching low levels during the summer period. Much of the winter precipitation occurs as snow and accumulates in snowdrifts which probably attain maximum depths of 2 to 3 m. (70 to 120 in.) based on a snowcourse at Oldman Pass (U.S. So-

July minimum -3.7°C. (25.3°F.)
Maximum temperature ... 26.9°C. (80.5°F.)
Annual precipitation ... 2,528 mm. (99.51 in.)
1st August
Snow depth 119 mm. (4.67 in.)

temperatures are undoubtedly considerably lower than in the natural area and annual precipitation somewhat higher on the natural area.

Plots in the natural area are generally characterized by distinctive A2-B2 sequences; they have not been mapped or classified into seral stages. A typical profile from the natural area tract had the following horizon sequence: 01 and 02, 6 to 0 cm.; A2, 0 to 3 cm.; IIB2b, 3 to 6 cm.; IIB2b, 6 to 11 cm.; A2, 11 cm. plus. The A2 has developed into a St. Helens "W" pumice which is 10 to 15 years in age (Crandell 1969); the profile was developed from andesite tephra.²

Plots (215 acres) of the Sister Rocks Natural Area are classified as SAF 226, Pacific Silver Fir-Hemlock (Cronquist et al. 1954). The plots within Küchler's (1964) Types 33, Fir-Hemlock or Fir-Hemlock and the *Abies amabilis* Zone of Cronquist and Dyrness (1969).

Pacific silver fir dominates the natural area, frequently occurring in pure stands (Type 2). Western hemlock (*Tsuga heterophylla*) is the most common associate (fig. 1). Douglas-fir (*Pseudotsuga menziesii*) is absent at higher elevations but occurs occasionally to common in some lower elevations; on local type maps, there are 59 acres on which Douglas-fir is a component. Noble fir (*Abies procera*) is scattered throughout the area, and the

Pacific silver fir in a young stand on the southern edge of the natural area; this small segment is part of a larger area (outside the natural area) which was burned by a wildfire in 1902 (fig. SR-2).

Pacific silver fir in the natural area is typically 65- to 100-cm. (25- to 40-in.) d.b.h. and 36 to 43 m. (120 to 140 ft.) tall. Stand analyses of similar Pacific silver fir growth nearby suggest a wide range of ages, with 250 to 350 years most common.³

Pacific silver fir is clearly the climax tree species throughout the natural area, based upon size class distributions and reproductive success. Consequently, pure, uneven-aged Pacific silver fir stands are the hypothetical climax here, and much of the area already approximates this structure and composition. Douglas-fir and noble fir occur only as large old individuals; in many areas, they are present as dead or dying specimens or stumps and down logs. The relatively tolerant western hemlock is likewise failing to produce in significant numbers and is primarily represented by old, overmature specimens.

Based upon Franklin's (1966) classification of the subalpine forests in this part of the Cascade Range, there are three major community types within the natural area: 1) *Abies amabilis*/*Streptopus curvipes* (*Ethronium montanum* phase) and *Abies amabilis*/*Vaccinium alaskaense* Association and an *Abies procera*/*Xerophyllum tetrasperum* community. The *Abies amabilis*/*Streptopus curvipes* Association is most common in the central portion of the natural area. This community has well-developed shrub and herb layers. *Vaccinium ovalifolium*, *V. alaskaense*, *V. membranaceum*, and *Menziesia ferruginea* are the dominant shrubs. The abundant herbs include *Tiarella unifoliata*, *Rubus pedalis*

cerns are the most common mosses. The *amabilis/Vaccinium alaskaense* Association is typical along the lower margins of the area. *Vaccinium alaskaense*, *V. membranaceum*, *Cornus canadensis*, *Berberis* *sa*, *Xerophyllum tenax*, *Chimaphila* *lata*, and *Rhytidiopsis robusta* are common constituents. The *Abies procera/Xerophyllum tenax* community is a pioneer type that characterizes the small area of 50-year-old forest found at the southern margin of the study area. *Xerophyllum tenax* and *Vaccinium membranaceum* are the most abundant understory plants.

Animals believed to utilize the natural area as residents or transients are listed in Table SR-1.

HISTORY OF DISTURBANCE

Human construction has caused, and will continue to cause, some disturbance along the margins of the natural area and, in connection with clearcutting of adjacent lands, will promote edge effects. However, most of the area is free of human disturbance except for the trail. The trail is used occasionally by berry pickers, and hunters. There is evidence that wildfires have occurred within the natural area for several centuries outside of the strip of 1902 burn which was included to provide a contrast with the old-growth stands.

RESEARCH

The Sister Rocks Research Natural Area has been used as a sampling site for studies of subalpine forests and soils in the southern Washington Cascade Range (Franklin 1961) and for a study of characteristics and distribution of Recent pumice and ash fall deposits.

This natural area is particularly valuable as a site for studies of the ecology of the silver fir, offering a variety of stand types and conditions, including pure stands and a recently burned area.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the study area include: *Topography*—15' Lookout Mountain, Washington quadrangle, scale 1:50,000, issued by the U.S. Geological Survey in 1961; and *geology*—*Geologic Map of Washington*, scale 1:500,000 (Hunting et al. 1961). The District Ranger (Wind River National Forest District) or Forest Supervisor (Gifford Pinchot National Forest, Vancouver, Washington) can provide details on the most recent aerial photo coverage and forest type maps for the area.

LEGEND

BOUNDARY SISTER ROCKS RESEARCH NATURAL AREA

Figure SR-2.—Communities of the Sister Rocks Research Natural Area. Upper left: Pure stand of Pacific silver fir with dense reproduction 0.5 to 1 m. tall. Upper right: Mixed stand of Pacific silver fir and western hemlock, the latter represented only by large, overmature specimens. Lower left: Noble fir/*Xerophyllum tenax* community growing on area burned by wildfire in 1902, located at the southern edge of the natural area. Lower right: Mixed stand of Pacific silver fir, Douglas-fir, western hemlock with abundant seedlings, saplings, and poles of Pacific silver fir.

TURNBULL PINE RESEARCH NATURAL AREA¹

ponderosa pine/bunchgrass savanna and pothole lakes and ponds characteristic of east central Washington.

Turnbull Pine Research Natural Area established December 1966 to exemplify a pristine ponderosa pine (*Pinus ponderosa*) savanna at the transition from forest to shrubland and a series of freewater potholes characteristic of the Channeled Scablands on the basalt plateau of east-central Washington. The 81-ha. (200-acre) tract is located in Spokane County, Washington, and administered by the Turnbull National Wildlife Refuge (Route 3, Box 107, Cheney, Washington), Bureau of Sport Fisheries and Wildlife. The irregularly shaped tract is located in section 25, T. 21 N., R. 43 E., 114th meridian, at 47°27' N. latitude and 117°30' W. longitude (fig. TP-1).

ACCESS AND ACCOMMODATIONS

The natural area is located 2.5 km. (1.5 mi.) south of Cheney, Washington, along the Cheney-Plaza County road which forms the tract's west boundary. Access is excellent during the summer and generally good during winter. Public accommodations are avail-

ranges from 685 to 715 m. (2,250 to 2,350 ft.) in elevation. Topography is generally rolling to rolling except around the potholes and lakes which are often surrounded by steep slopes or rock cliffs (fig. TP-2).

The natural area is located on the eastern edge of Washington's well-known Channeled Scablands (Bretz 1959). The Columbia River basalts which characterize the entire Columbia Plateau provide the foundation for the landscape. An intricate network of drainage channels are carved into this bedrock and are overlain by a heavy overburden of loess. Glacial damming of the Columbia River by a lobe of the continental ice sheet is believed to have combined with successive massive floods released from artificially dammed lakes to produce the scablands. The natural area itself was probably never actually glaciated.

A modified maritime climate prevails. Most precipitation occurs as rain or snow during the cool, cloudy winter. Summer is warm, generally low in precipitation and largely cloudless. One to 3 months of drought are common. Climatic data from Spokane, about 29 km. (18 miles) north, are as follows (U.S. Weather Bureau 1965):

Mean annual temperature	8.8°C. (48°F.)
Mean January temperature	-3.7°C. (25°F.)
Mean July temperature	21.4°C. (71°F.)
Mean January minimum temperature	-7.7°C. (18°F.)
Mean July maximum temperature	28.7°C. (84°F.)
Average annual precipitation	437 mm. (17.2 in.)
June through August precipitation	56 mm. (2.2 in.)
Average annual snowfall	147 cm. (5.8 in.)

stones to a depth of up to 10 dm (4 in.). The basalt bedrock. Minor areas of other Hesseltine-type soils also occur. The Hesseltine soils are typically forested. Soils in the meadows and around pothole borders are the Cocollala silty clay loam. This soil ranges up to 14 dm. (60 in.) deep and is formed in volcanic ash deposits mixed with silty alluvium. Highly organic Semiahmoo muck soils are found in the potholes (e.g., in fig. TP-2), which suggests natural pond succession and eutrophication.

BIOTA

Estimated areas by vegetation type are as follows:

Name	Area
Ponderosa pine forest	65 ha. (160 acres)
Grassland	8 ha. (20 acres)
Quaking aspen	4 ha. (10 acres)
Aquatic (kettle lakes and potholes)	4 ha. (10 acres)

The forest stands are assignable to SAF forest cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and Küchler's (1964) Type 11, Western Ponderosa Forest. The grasslands best fit Küchler's Type 51, Wheatgrass-Bluegrass with some Type 50, Fescue-Wheatgrass. The kettle lakes and potholes with their associated meadow vegetation would probably fit Küchler's Type 49, Tule Marshes. The natural area falls in a zone of ponderosa pine savanna where ponderosa forests gradually grade into Columbia Basin bunchgrass.

Ponderosa pine (*Pinus ponderosa*) forests may be divided into two community types: *Pinus ponderosa*/*Festuca idahoensis* and *Pinus ponderosa*/*Symphoricarpos albus*/*Calamagrostis rubescens*. The *Pinus*/*Festuca* type is characteristic of convex topography and shallower soils. Pine crown cover varies

related to Daubenmire and (1968) *Pinus ponderosa*/*Festuca* Association.

The *Pinus*/*Symphoricarpos* community type is characterized by concave microtopography and wet bottoms (fig. TP-2). Pine crown cover from 35 to 50 percent. Ground is codominated by *Symphoricarpos* and pinegrass (*Calamagrostis rubra*). Other important components are Idaho sedge (*Carex geyeri*), and *Fragaria* var. *platypetala*. This community clearly fit any of Daubenmire and Daubenmire's (1968) associations. It is a variant of their *Pinus ponderosa*/*Symphoricarpos albus* Association in which pine is far more important than the sedge. I recognize. Variations in microtopography and soil depth seem related to the forest communities.

Quaking aspen (*Populus tremula*) communities occasionally occur in the forest (fig. TP-2) and as stringers are found in meadows. Quaking aspen is clearly associated. Associated vegetation is *Solidago* spp., thinleafed lupine (*Lupinus tenuifolia*), water birch (*Betula nana*) and *Cornus stolonifera*.

The grasslands generally occur on the surfaces of the gentle, undulating topography and appear associated with shallow soils (fig. TP-2). Other than very occasional ponderosa pine, they are dominated by bluegrass, Idaho fescue, and *Bromus* spp. on deeper soils. On shallower soils they are dominated by Sandberg bluegrass (*Poa sandbergii*) spp. with some Idaho fescue and wheatgrass.

The 4 ha. (10 acres) of kettle lakes are characterized by fringing vegetation which retain their water all

P-2). Western yellow pond lily (*Nuphar palus*) often colonizes free-water areas. are often edged by wet meadows char-ized by tule (*Scirpus accutus* and/or *idus*) with occasional colonies of cattails (*a latifolia*). Where moisture and free are less abundant, the tule grades into meadow dominated by *Phalaris arun-a*, which is often associated with *Des-sia caespitosa*. Most pothole lakes are nded by rock ledges or steep slopes 0 to 25 feet high (fig. TP-2).

imals believed to utilize the natural s residents or transients are listed in TP-1. A list of resident and transitory can be obtained from the Refuge ger.

HISTORY OF DISTURBANCE

e scars on ponderosa pine indicate d fires periodically burned the area o fire control programs.

ARCH

e research is being conducted by ecology ts at nearby Eastern Washington State e, Cheney, Washington. Information e obtained from the Refuge Manager or the Biology Department of Eastern ngton State College. Voucher specimens e birds and animals and most plant s are available for inspection at Refuge uarters.

natural area provides unique oppor-s to study: (1) the ecology of pothole and their associated meadow vegetation

under undisturbed conditions; (2) int-between dry upland nonforested veg-and forested vegetation on slopes and b-forest and meadow and meadow ar-water; (3) relationships of faunal distribution to vegetation over these ex-ly variable environmental condition- (4) aquatic communities.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic are available for the natural area wh-sufficiently detailed to be useful. The Manager (Turnbull National Wildlife l-Cheney, Washington) can provide det-the most recent aerial photo cover-the area.

Since refuge establishment in 1937, g-tree cutting, and other disturbance- been prohibited on the original 20 l-acres) of this natural area (the northv-corner of the present tract). The natur-was expanded to 81 ha. (200 acres) i-and the 61-ha. (150-acre) addition h-ceived some light use by cattle eac-between 1937 and 1968. The old-grow-derosa pine was logged prior to Refi-tablishment, and present forest stan-sapling and pole sized with occasional-trees. Domestic livestock also used th-sometimes heavily, prior to Refuge est-ment. The abundance of *Bromus* spp. su-livestock overuse produced some modif-of ground vegetation.

TWIN CREEK RESEARCH NATURAL AREA¹

"Rain forest" Sitka spruce-western
hemlock stands growing on terraces
along the Hoh River on the western
Olympic Peninsula, Washington.

The Twin Creek Research Natural Area
was established in 1958 to exemplify Sitka
spruce (*Picea sitchensis*) forests as they occur
under the "rain forest" conditions found in
the valleys on the west side of the Olympic
Peninsula. The 40-ha. (100-acre) tract is
located in Jefferson County, Washington, and
is administered by Olympic National Park
(Port Angeles, Washington). The natural
area is located in two units which occupy
portions of sections 20, 21, and 29, T. 27 N.,
R. 12 W., Willamette meridian. Legal lines
define the boundaries. The tract is located
at 48° 50' N. latitude and 124° 00' W. longitude.

ACCESS AND ACCOMMODATIONS

The natural area is located a short distance
from the Hoh River Road, about 23 km. (14
miles) from its junction with U.S. Highway
2. The west unit is located about 1.6 km.
(1 mile) inside the park boundary and 9 km.
(5.5 miles) from the visitors center at the
end of the Hoh River Road. The east unit is
located about 1.6 km. (1 mile) east of the west
unit. There are no trails within the natural

area, from 40 to 56 km. (25 to 35 miles).
However, there is an excellent public
campground at the end of the Hoh River Road.
Several smaller State campgrounds are
located along the road outside the park.

ENVIRONMENT

The natural area occupies gentle topography
on river terraces in the Hoh River valley.
Elevations range from about 130 to 150 m.
(420 to 640 ft.) in the west unit and 150 to 180
m. (500 to 580 ft.) in the east unit. The
tributaries of Twin Creek flow through the
valley of the east unit and swampy areas are
found in both units of the natural area (TW-1).

The natural area is located on
Cretaceous-lower Tertiary sedimentary rocks
belonging to the Soleduck formation (Calkin
1955, Huntington et al. 1961); however, the
rock is completely buried beneath deposits
of alluvium and possibly some glacial drift.
The valley of the Hoh River, including the
natural area, has been glaciated at least
three times during the Wisconsinan age and
at least once in pre-Wisconsinan time (Calkin
1964).

A wet, mild, maritime climate prevails.
Winters are mild and summers are cool with
frequent cloudy days. Precipitation is high,
but less than 10 percent falls during summer
months. The following climatic data are from
the Forks weather station located approximately
32 km. (20 miles) northwest of the
natural area (U.S. Weather Bureau 1961).

precipitation is significantly higher than the natural area itself, probably averaging about 100 mm. (142 in.) annually (Kirk 1966).

Soils appear to be predominantly Sols as Acides. Fonda² has described profiles of similar terrace areas in the vicinity of the natural area and found the following sequence typical:

0 to 2 cm.	Fresh litter.
2 to 16 cm.	Very dark grayish brown with moderate crumb structure.
16 to 46 cm.	Very dark gray sand, compact breaking to single grain.
46 to 57 cm.	Very dark gray sand with single grain to weak crumb structure and some clay accumulation.
57 to 150 cm.	Black sands with single grain structure.
150 cm. +	River cobbles and gravels.

NOTA

Essentially all the forest within the natural area can be considered a mixture of SAF forest cover types 225, Sitka Spruce-Western hemlock, and 223, Sitka Spruce, with the latter type probably dominant (Society of American Foresters 1954). They belong to Schler's (1964) Type 1, Spruce-Cedar-Hemlock Forest. The tracts are located within the *sea sitchensis* Zone of Franklin and Dyrness (1969). Categorizing the area in this manner does not do it justice, however; it is an example of the so-called "Olympic Rain Forest" found on major river terraces on the west side of the Olympic Peninsula (Kirk 1966).

The two units are mosaics of Sitka spruce and western hemlock (*Tsuga heterophylla*) forest of varying ages and sizes interspersed with open areas dominated by vine maple (*Acer circinatum*) and occasionally bigleaf

all size classes ranging up to a diameter of 230- to 330-cm. (90- to 130-in.) of spruce and 100- to 150-cm. (40- to 60-in.) for hemlock. Mature trees of either can obtain heights of 60 m. (200 ft.) and more. Bigleaf maple and Douglas-fir (*Pseudotsuga menziesii*) occur in more localized portions of the natural area. Bigleaf maple can obtain diameters of 75 to 100 cm. (30- to 40-in.) b.h. and heights of 15 to 21 m. (50- to 70-ft.). Douglas-fir is largely confined to the steep terrace faces found towards the edge of both of the units.

The forests in the natural area appear to be near climax condition. Although Sitka spruce is considered a subclimax species in the *sea sitchensis* Zone of Franklin and Dyrness (1969), this does not appear to be the case in this area. Spruce seedlings and saplings are small poles are encountered throughout the area. Climax status is probably the result of consequence of the special conditions of the "rain forest" valleys of the western Olympic Peninsula, particularly the relative stability of nature of many of the stands and the absence of grazing of hemlock seedlings by elk. Tree reproduction is found on rotten "nurse logs," which often support the growth of hemlock and spruce seedlings. Many of these survive, and their roots reach the surface soil. The consequences are visible throughout the natural area as lines of mature trees growing on remains of original natural forest and in the stilted root systems of mature spruce and hemlock.

Forest stands have relatively rich understories. Vine maple (*Acer circinatum*), *V. parvifolium*, *R. ursinus*, and *R. spectabilis* are the most common species in the shrub layer. Vine maple is clearly the most important. Relative abundance of *Rubus spectabilis* compared to maple

Polystichum and *Polystichum dryopteris*. *Polystichum* and *Polystichum* are clearly the most important herbs. The "rain forest" region of the western Olympic Peninsula is famous for an abundance of bryophytes, and the natural area is no exception. Mosses, liverworts, and lichens grow on the ground, downed logs, shrubs, and tree trunks. Some of the more common bryophyte species are *Eurhynchium oregonum*, *Platydictyon circinale*, *Rhytidiadelphus loreus*, *Platydictyon menziesii*, *Hylocomium splendens*, *Platydictyon insigne*. One of the most conspicuous epiphytes is the club moss, *Selaginella selaginoides*, which is particularly abundant on the trunks of the maples. Other common epiphytes are *Loisothecium stoloniferum*, *Porella navicularis*, *Rhytidiadelphus loreus*, *Radula borinquensis*, *Frullania nisqualensis*, *Scapania peruviana*, and *Ptilidium californicum*.

The Roosevelt elk (*Cervus canadensis roosevelti*) is the most important animal present. The elk use the natural area most heavily during winter and spring. Other mammals believed to utilize the area as residents or visitors are listed in table TW-1.

Indian Creek provides some area of aquatic habitat in the east unit of the natural area. As mentioned, both units contain open meadowy area, providing additional specialized habitat for a variety of plants and animals typical of heavily forested areas. These meadowy areas have standing water for at least a portion of the year.

HISTORY OF DISTURBANCE

Human disturbance appears to be very recent despite the proximity of the area to the Hoh River Road. There is no evidence of fires within the tract within the last several centuries.

RESEARCH

The only research known to have been conducted within the natural area are the vegetation level examinations of the site in connection with a study of relationships between forest communities and environmental conditions in the Hoh River Valley.

The natural area appears to offer unique good opportunities for research on: (1) successional development in coastal rain forest, particularly the relative successional stages of Sitka spruce and western hemlock; (2) effect of Roosevelt elk on community composition and forest succession; and (3) ecology of epiphytic mosses, club mosses, liverworts, and lichens.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area include: *Topography*—15' Spruce Mountain and Mount Tom, Washington quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1956 (Spruce Mountain quadrangle covers the west unit and Mount Tom quadrangle covers the east unit of the natural area); *Topographic Map of Olympic National Park and Vicinity*, Washington, scale 1:62,500, issued by the U.S. Geological Survey in 1956; and *geology*—*Geologic Map of Washington*, scale 1:500,000 (Huntington et al. 1961). The Superintendent, Olympic National Park, Port Angeles, Washington, can provide details of the most recent aerial photo coverage and forest type maps for the area.

⁴ Research by Dr. R. W. Fonda, Department of Biology, Western Washington State College, Bellingham.

WILDCAT MOUNTAIN RESEARCH NATURAL AREA¹

stands of noble fir and associated
species on mountain slopes and
ridgetops in the western Cascade
range of Oregon.

Wildcat Mountain Research Natural
Area was established on March 18, 1968, to
provide prime examples of noble fir (*Abies
noble*) stands as they occur on mountain
slopes in the western Cascades of Oregon. The
Area (1,000-acre) tract is located in Linn
County, Oregon, and is administered by the
McKenzie Bridge Ranger District (McKenzie
Bridge, Oregon), Willamette National For-
est. The tract occupies portions of sections
21, 22, 27, and 28, T. 14 S., R. 6 E.,
Willamette meridian (fig. WM-1). The south-
western boundary is marked by Forest Road 147
along the dividing ridge between Browder and
Bunchgrass Creeks (fig. WM-1). The northern
boundary is based on various natural features
marked either directly or as control points. It
is at 44°20' N. latitude and 122°06' W.
longitude.

ACCESS AND ACCOMMODATIONS

The easiest to approach the vicinity from
the north (Albany and Sweet Home),
U.S. Highway 101, is the most direct route.

Tombstone Summit onto Forest Road 147
and follow it to Forest Road 147 and
natural area. From U.S. Highway 126
north onto Forest Road 1645 (about 1
or 9 miles east of McKenzie Bridge
Station). The natural area can be reached
from this and Forest Road 1345 or via Forest
Road 147 which leaves Forest Road 1645 about
1.5 km. (1.5 miles) north of U.S. Highway 101.

Forest Road 147 provides access to the
southern edge of the natural area, and an
abandoned Wildcat Mountain trail traverses
the western half, terminating at the summit
of the mountain.

ENVIRONMENT

The Wildcat Mountain Research Natural
Area extends across the summit ridge of
Wildcat Mountain onto the north slope of
Bunchgrass Mountain (fig. WM-1). Eleva-
tions range from about 1,160 m. (3,800 ft.)
at the bottom of a drainage in section 21
to 1,632 m. (5,353 ft.) at the summit of
Wildcat Mountain. Several distinctive topo-
graphic units can be recognized: (1) the south-
western face of Wildcat Mountain which has moderate
(20- to 40-percent) slopes at its base and be-
comes increasingly steeper (50- to 70-percent)
slopes near the summit; (2) the north-
western face of Wildcat Mountain which is largely
steep or precipitous (50- to over 100-percent)
slopes and has frequent rock outcrops; and
(3) the drainages on the north slope of Bunch-
grass Mountain and associated ridges which
have steep (30 to 80 percent) but generally

sites (Peck et al. 1964). However, recent studies indicate that "... these areas of 'High Cascade' rocks which have been mapped within the Western Cascade Province are not to be associated in time or in place of origin with High Cascade volcanism." (Taylor 1968). Topographically the natural area is certainly consistent with the deeply eroded character of the western Cascades, and it lies several kilometers west of the recognized boundary (approximately the McKenzie River) between the western and high Cascades.

The dominant rock type is andesite. Volcanic tuffs, breccias, and possibly, intrusive plugs and dikes also occur in the area. Peck et al. (1964) have provided some data on the lithology and petrography of the volcanic bedrock. Residual materials are covered with aeolian deposits of volcanic ash except where the ash has been removed by erosion. The source and age of the ash deposits are unknown, but there are many possible vents in adjacent parts of the high Cascades (Taylor 1968).

The wet, cool climate of the natural area is typical of subalpine areas in the Cascade Range. Precipitation is heaviest during the winter months (November through March); only 4 to 5 percent occurs during the summer (June through August). About half of the precipitation occurs as snow and accumulates in winter snowpacks which reach maximum depths of 2 to 3 m. (70 to 120 in.) between February and March. The peak of snowmelt typically occurs in May and is completed by June or early July. There are no nearby climatic stations which provide useful climatic indices for the natural area. However, headquarters of the U.S. Army Corps of Engineers' Willamette Basin Snow Laboratory was located in the pass between Squaw and Wildcat Mountains, about 1 km. (0.5 mile) west of the

Mean January temperature	...
Mean July temperature
Average annual precipitation	..
June through August precipitation
Snowfall (water equivalent)	..

Since the mean elevation of the study is 1,045 m. (3,430 ft.), lower on the natural area and higher; an isohyetal map shows 4,065 mm. (150 to 160 in.) of precipitation on the natural area of Engineers North Pacific Division. The numerous data collected at the Willamette Basin Snow Laboratory and the "Snow Hydrology: Summary of Snow Investigations" (U.S. Army Corps of Engineers North Pacific Division) are on file at the division in Oregon.

Soils in the area are poor Podzolics. In some locations one can discern any profile development; however, the surface 15 to 20 cm. of soil is a weakly expressed, dark brown, or sandy loam with weak structure. This soil material is "fluffy" and is always of low density. Soil texture usually changes throughout the profile, increasing with depth and becoming 60 percent by volume at 40 cm. (15.75 in.) to 23.62 in.). Despite abundant organic matter in the profile these soils are largely derived from aeolian volcanic ash. Forest floor thickness is 4 to 8 cm. (1.5 to 3 in.) and is underlain by a very thin, organic horizon.

WM-1. Areas of SAF cover types can be summarized as follows:²

Name	Area
Pacific Silver Fir-Hemlock (noble fir-dominated)	209 ha. (517 acres)
Pacific Silver Fir-Hemlock (Pacific silver fir-dominated)	38 ha. (95 acres)
Mountain Hemlock-Subalpine Fir	22 ha. (55 acres)
Douglas-Fir-Western Hemlock	17 ha. (43 acres)

There are 117 ha. (289 acres) of nonforested areas within the natural area, which include cliffs, meadows of various types, and fields (fig. WM-2). Kuchler (1964) types represented include Silver Fir-Douglas Fir (3) and Fir-Hemlock Forest (4). Most of the natural area lies within the *Abies* Zone; the *Tsuga mertensiana* Zone is represented at higher elevations (Franklin and Yrnes 1969).

The most important and nearly ubiquitous species in the natural area is noble fir. The 130-year-old stands located in the southern quarter and 300-year-old stands in the eastern third of the natural area provide excellent examples of this species. Pacific silver fir (*Abies amabilis*), Douglas-fir (*Pseudotsuga menziesii*), and mountain hemlock (*Tsuga mertensiana*) are common associates. The silver fir is absent from the overstory of the pure noble fir stands but is present everywhere as seedlings and saplings; few stands at highest elevations Pacific silver fir and mountain hemlock are the only species present. Douglas-fir is most abundant in the drainage in section 22 and is nearly absent at higher elevations. Some of the 130-year-old stands contain residual 450-year-old Douglas-fir specimens which survived the action of the previous stand; young,

generally subordinate in the crown canopy, dominant noble firs.

Other tree species present within the natural area are western white pine (*Pinus monticola*), Alaska-cedar (*Chamaecyparis nootkensis*), and western hemlock (*Tsuga heterophylla*). The pine is scattered throughout the area, but much of it is presently dead or dying from attacks by bark beetles and white blister rust. Alaska-cedar is generally confined to rocky habitats along the ridgetops around some meadow areas. Western hemlock is essentially confined to lower elevations.

Mensurational data have been collected only from the younger forest stands within the natural area. Dominant noble fir in the productive southwestern part of the natural area average 75- to 100-cm. (30- to 40-in.) d.b.h. and 50 to 55 m. (160 to 180 ft.) tall. Ring counts on roadside stumps indicate a range in age from 120 to 137 years; these data substantiate the age class recognized in the 1960 inventory. Douglas-fir of the same age in these stands average 15 to 30 cm. (6 to 12 in.) smaller in diameter and 2 to 5 m. (6 to 15 ft.) shorter than the dominant noble fir. The scattered old-growth Douglas-fir in the area commonly 125- to 150-cm. (50- to 60-in.) d.b.h. and about 450 years old. Douglas-fir, Pacific silver fir and mountain hemlock growing on poorer sites average 30- to 40-cm. (12- to 24-in.) d.b.h. and 30 to 35 m. (100 to 120 ft.) tall at 120 to 130 years. Trees in stands over 130 years of age are, of course, larger in size, given comparable site conditions. Maximum diameters observed are 186.7 cm. (73.5 in.) at b.h. for noble fir and 91.4 cm. (36.0 in.) b.h. for Pacific silver fir.

Based on size class distributions, mensurational trends apparently favor gradual replacement of most forest tree species

species in intermediate size classes. In stands, Pacific silver fir commonly dominates both seedling and intermediate size classes (fig. WM-3). Pacific silver fir seedlings and saplings are also much more abundant than those of mountain hemlock in mixed stands of these species. In general, noble fir is failing to reproduce within closed forest stands; however, seedlings are abundant on the forest floor after a good seed year and may persist for several years before dying. Mountain hemlock and Douglas-fir also appear ineffectual in reproducing themselves in forest stands.

At least four major forest communities can be recognized within the natural area based on the limited sampling thus far: *Abies procera*/*Clintonia uniflora*, *Abies procera*/*Achlys triphylla*, *Tsuga mertensiana* - *Abies amabilis*/*Xerophyllum tenax*, and *Abies amabilis*/*Vaccinium membranaceum* - *Xerophyllum tenax*.³

The *Abies procera*/*Clintonia uniflora* community is found on productive, relatively mesic sites. It is characterized by a herb-rich understory which averages 40- to 45-percent canopy coverage; in some dense stands the coverage is much less (fig. WM-3). Typical species include *Achlys triphylla*, *Anemone deltoidea*, *Chimaphila menziesii*, *C. umbellata*, *Clintonia uniflora*, *Cornus canadensis*, *Galium oreganum*, *Pyrola picta*, *P. secunda*, *Pteridium aquilinum*, *Rubus lasiococcus*, *Smilacina sessilifolia*, *Tiarella unifoliata*, *Viola glabella*, and *V. sempervirens*. *Cornus*, *Smilacina*, and *Clintonia* usually have the highest coverage of herbaceous species. *Vaccinium membranaceum* has high constancy, but its coverage is relatively low (1 to 15 percent).

Abies procera/*Achlys triphylla* communities are found on somewhat poorer sites, e.g., areas of shallower soil. Vine maple (*Acer*

coverage. The herbaceous understory is relatively well developed and includes *Achlys triphylla*, *Pyrola* spp., *Smilacina* spp., *Galium oreganum*, *Viola glabella*, and *V. sempervirens*. The *Achlys* and *Smilacina* spp. have the highest herbaceous coverage.

The *Tsuga mertensiana* - *Abies amabilis*/*Xerophyllum tenax* community is found in the poorest forested habitats, on the shortest, coolest growing sites and shallow soils. Only two species are found in the understory — *Xerophyllum tenax* and *Vaccinium membranaceum*. The herbaceous *Xerophyllum tenax* community has significant coverage of *Vaccinium membranaceum* with canopy coverage of 40- to 60-percent (fig. WM-3).

A fourth forest community, *Abies amabilis*/*Vaccinium membranaceum* - *Xerophyllum tenax*, is at least partially represented in the natural area. It is distinguished in character between the *Xerophyllum tenax* community and the *Abies*/*Clintonia* community by significant coverage of *Vaccinium membranaceum*, *Xerophyllum tenax*, and *Viola glabella*.

There are also a variety of other communities in the Wildwood search Natural Area. These include (1) meadows on logged and burned sites, (2) meadows of various types, (3) communities with rock outcrops and clearcuts, (4) areas clearcut and burned in 1952 (in section 20) and 1953 (in sections 21 and 28) were incorporated into the natural area. The seral communities in these areas are typical of early succession on forest habitats. *Ceanothus velutinus* dominates the (more advanced) clearcut areas, and other. Natural regeneration

organic soil has developed; it is rare in the natural area, occurring most frequently adjacent to Sitka alder (*Alnus* spp.) thickets. Typical dominants are *Vernonia*, *Senecio triangularis*, and *Valeriana*. The Mesic Meadow type is a habitat where moisture is typically high until midsummer. Dominants are *Erigeron parviflorus*, *Pteridium aquilinum*, and *Chenopodium occidentale*. There are many associated herbaceous perennials, e.g., *Erigeron*, *Lupinus latifolius*, *Polygonum physocarpum*, *Cirsium centauria*, and *Vicia* spp. var. *truncata*, and occasional annuals, e.g., *Gayophytum humile*. This type of meadow is probably the most common within the natural area. In some areas, invasion of trees, especially noble fir, is taking place; in others, there is no invasion for such successional changes, and the meadow community appears stable. Subserotinous Meadows occur on sites with thin, rocky soils where moisture becomes limited relatively early in the growing season. Representative species are *Gilia aggregata*, *Gayophytum diffusum* var. *parviflorum*, *Thymus imbricatus*, *Polygonum douglasii*, *Navarretia divaricata*, *Microsteris* spp., *Collinsia parviflora*, *Cerastium arvense*, and *Rumex acetosella*.

On sites adjacent to the meadows and on steep, north-facing slopes on Wildcat Mountain, and talus associated with rock outcrops are occupied by shrub communities. Elder is the typical dominant on wetter sites and steep north slopes forming dense thickets. Deep winter snow accumulation and extensive snow creep cause strong shading of the 3- to 5-m.-(10- to 16-ft.-) stems. In a nearby area, the occurrence of these stands has been related to higher water tables due to a nearly impervious

communities occupying relatively dry talus slopes, in some cases, with Sitka alder communities which may be found on small portions of the same talus patch. Both types of shrub communities appear to be stable community types as there is general evidence of encroachment by tree species.

The communities found on rock outcrops and cliffs have not been examined. The communities present undoubtedly include many of those listed by Hickman (1968) for the Olympic Ridge and Vertical Outcrop habitats. Described in his floristic study of the western Cascades. The Outcrop Ridge habitat is found on south- and west-facing slopes, where wasting of small fragments has produced small outcrops of barely exposed parent rock eroded parallel to the general slope of the area. Many species root in weathered rock or pockets of finer material, including *Phacelia menziesii* var. *pyramidalis*, *Penstemon procerus* var. *bicolor*, *Penstemon*, *Sedum stenopetalum* and *S. divaricatum*, *Eriophyllum lanatum*, *Arctostaphylos* spp., *Comandra umbellata*, *Lomatium* spp., *Sanicula graveolens*, *Eriogonum compositum*, *Juniperus communis*, *Eriogonum foliosum* var. *confinis*, *Arenaria capillaris* var. *americana*, *Erysimum asperum*, and *Phacelia heterophylla*. Species such as *Saxifraga* spp. var. *vespertina* and *Penstemon* spp. are typical of the exposed Vertical Outcrop habitat.

Mammals believed to utilize the natural area as residents or transients are listed in table WM-2.

The only specialized habitats known to occur on the natural area, which have not already been mentioned, are the live stream and streamside areas.

dense tree regeneration. Sheep grazing is frequent in mountain meadows in this part of the Cascade Range into the 1930's. This has undoubtedly influenced the character of the various meadows found within the natural area.

Most human disturbance is along the southern margin of the area although it is considered minor; this area will probably also be the focus of any future problems. Two small areas (fig. WM-1) totalling about 4 ha. (10 acres) were clearcut prior to natural area establishment. Some mortality (mostly wind-throw) is associated with the margins of these clearcuts and of Forest Road 147, particularly immediately northwest of the Wildcat-Bunchgrass Mountain saddle. Some damage from road construction (sidecast dirt and rock) also occurred in this area.

Natural disturbances appear to be minor within the natural area since the bulk of the stands were established 130 years or more ago. The scattering of younger stands suggests some minor wildfires have occurred in the last 50 years. Dwarf mistletoe is present in noble fir in at least some of the area, and there also appear to be small scattered pockets of root rot.

RESEARCH

A number of research projects are already in progress at Wildcat Mountain Research Natural Area:

1. Cone production by noble fir has been observed annually since 1961 (Franklin 1968) and that by mountain hemlock and Pacific silver fir since 1967.⁵ This study will continue until at least 1972.

2. Total amount and quality of annual needlefall has been under study since 1968, and this research will continue until at least

silver fir stand at about 1,430 m. (4,700 ft) on the north slope of Bunchgrass Mountain (WM-3).

3. Vegetation-soil plots (10) have been taken within the natural area as part of a study of the forest communities and their environmental relationships in the western Cascades of Oregon. These plots are incorporated into the resulting classification.

4. Numerous collections of soil samples have been made within the natural area by Forest Service and Oregon State University ecologists.⁸

5. Stem analyses of noble fir and Douglas-fir species have been made on specimens collected immediately adjacent to the natural area. Both the least and most productive stands are represented in these samples. The samples are presently being analyzed (DeMars and Bell 1970; Herman and DeMars 1970).

This natural area is considered representative to the H. J. Andrews Experimental Forest located 8 km. (5 miles) southwest. It provides an additional representation of high elevation true fir forest. The possibility exists of using comparable forest areas on the experimental forest for work involving destructive sampling or manipulation and using the natural area as a control site.

The H. J. Andrews Experimental Forest (including Wildcat Mountain Research Natural Area) is also an intensive study area for the U.S. International Biological Program's Coniferous Forest Biome and Ecosystems project. Two plots have been established in this ecosystem research are located within the natural area.⁹ One plot is located in a noble fir-Douglas-fir stand in the southern corner of the natural area and the other is located in a mountain hemlock-Pacific silver fir stand on the north slope of B

tain. At present, soil and air temperature, plant moisture stress, foliage nutrient content, and phenology are being monitored in these plots. Many additional studies are planned for 1972 and 1973. Small mammal populations are also under study within the main hemlock-Pacific silver fir stand.

The natural area provides a number of research opportunities besides those available in connection with already active research projects. These include research on: (1) the two small watersheds which occupy the eastern half of the area; (2) subalpine forests of varying age, composition, and productivity, including some of pure noble fir; (3) mountain meadows typical of those found in the western Cascades; and (4) succession on recently cutover tracts incorporated into the natural area.

MAPS AND AERIAL PHOTOGRAPHS

Special maps applicable to the natural area are: *Topography*—15' Echo Mountain quadrangle, scale 1:62,500, issued by the U.S. Geological Survey in 1955; and *Geology*—*Reconnaissance Geologic Map and Section of the Western Cascade Range, Oregon, of Latitude 43° N.*, scale 1:250,000 (McWilliams et al. 1964), *Geologic Map of the Central Part of the High Cascade Range, Oregon* (McWilliams 1957), and *Geologic Map of Oregon of the 121st Meridian*, scale 1:500,000 (McWilliams 1961). Either the District Ranger (McWilliams, Bridge Ranger District) or Forest Supervisor (Willamette National Forest, Eugene) can provide details on the most recent aerial photo coverage and forest type maps for the area.

WILLAMETTE FLOODPLAIN RESEARCH NATURAL AREA¹

Grassland and Oregon ash forest on
flood bottom lands in Oregon's Willa-
mette Valley.

The Willamette Floodplain Research Na-
tural Area provides an excellent example of
grassland-forest community mosaic found
in valley-bottom habitats or flood plains
in western Oregon's Willamette Valley. Orig-
inally established on December 27, 1966, to
preserve unplowed, near-natural grasslands,
which have since been relocated and enlarged to
include the typical flood plain forests of Oregon
(*Taxus latifolia*). The 97-ha. (239-acre)
area is located in Benton County, Oregon,
and is administered by the William L. Finley
National Wildlife Refuge (Route 2, Box 208,
Corvallis, Oregon), Bureau of Sport Fisheries
and Wildlife. It occupies portions of section
13 S., R. 5 W., Willamette meridian,
46° 26' N. latitude and 123° 18' W. longi-
tude (fig. WP-1).

ACCESS AND ACCOMMODATIONS

The natural area is located about 16 km.
(10 miles) south of Corvallis, a short distance
from U.S. Highway 99W. A graveled all-
weather road provides access to within a few
hundred feet of the west boundary; from

ground. Commercial accommodation
is available in Corvallis; there are no
campgrounds within the Refuge.

ENVIRONMENT

The Willamette Floodplain Research Na-
tural Area is located on essentially flat
topography typical of the floor of the Willa-
mette Valley. Elevation ranges from about
88 m. (270 to 290 ft.). Gentle swale
ridges, which are most easily distinguish-
able on aerial photographs, provide the or-
relief. Muddy Creek, a small, turbid, me-
andering, valley-bottom stream, flows through
the center of the area.

The natural area is located on valley
alluvium consisting of unconsolidated
sands and gravels (Vokes, Myers, and
Piper 1954). These alluvial materials belong
to a group known as the Willamette silts,
which are believed to be of the Wisconsin age
to a Recent group. Piper (1942) provides
additional details on these materials.

The natural area is located in western
Oregon, an area of mild, moist climate. How-
ever, it is within the Willamette Valley, which
is located between the Coast and Cascade Ranges
and is, therefore, subject to the somewhat
warmer and drier climate typical of interior
western Oregon valleys. The summer
period is especially pronounced. Repre-
sentative climatic data from the Corvallis weather
station, which is about 16 km. (10 miles)
north, are as follows (U.S. Weather Bureau
1965):

little descriptive work has as yet been laid out on the forest stands. Oregon ash is a major dominant but Oregon white oak (*Quercus garryana*) becomes a codominant or dominant in the stands located west of Muddy Creek (fig. WP-2). The Oregon ash stands vary considerably in age and in density and composition of understory. Some of the denser stands have essentially no ground vegetation. All of the lowland forest is, of course, subject to flooding by the overflow of Muddy Creek every winter.

Animals which are believed to occur on the Willamette Floodplain Research Natural Area residents or transients are listed in figure WP-1. The western pond turtle (*Pseudemys marmorata*) is found in Muddy Creek. A number of different bird species may be encountered within the natural area; a complete list of the birds for the Refuge is available from the Refuge Headquarters. Among those nesting in the natural area itself are all of the waterfowl which periodically feed on the area such as the dusky Canada goose (*Branta canadensis* var. *occidentalis*), for which the refuge was established, marsh hawk (*Nycticorax nycticorax*), short-eared owl (*Asio flammeus*), sharp-shinned hawk (*Buteo lineatus*), barred hawk (*Buteo lagopus*), western meadow lark (*Sturnella neglecta*), golden-crowned kinglet (*Troglodytes aedon*), vesper sparrow (*Zonotrichia atricapilla*), sharp-shinned hawk (*Buteo lineatus*), ring-necked pheasant (*Phasianus colchicus*), California quail (*Lophortyx californicus*), and mourning dove (*Columba macrourus*). Large numbers of mallards (*Anas platyrhynchos*) are encountered along Muddy Creek at certain times of the year.

DESCRIPTION OF DISTURBANCE

the southwestern corner of the natural area is an abandoned field which is gradually undergoing colonization by native plants; the area was abandoned some time prior to 1964.

RESEARCH

The only research conducted thus far on the Willamette Floodplain Research Natural Area is by undergraduate students in ecology and wildlife from Oregon State University. The Refuge Manager can provide details.

The natural area is a uniquely valuable research site. It is one of only two scientific reserves which includes stands of Oregon ash and provides the only protected example of seminatural, unplowed Willamette Valley grassland. Among the many opportunities for research include studies of: (1) succession processes, particularly in connection with the burning program planned for a portion of the natural area; (2) variation in community composition in relation to microtopography (swale vs. ridge); (3) the role of various introduced plant species; (4) long-term changes in the forest-grassland boundary; and (5) aquatic and semiaquatic organisms associated with the meandering valley stream.

MAPS AND AERIAL PHOTOGRAPHS

There are no special maps of sufficient detail to be of value. Aerial photographs taken in June 1970 are available from the Agricultural Stabilization and Conservation Service, Benton County ASC Committee, P.O. Box 1027, Corvallis, Oregon. The photo provides a good view of the natural area and its

WIND RIVER RESEARCH NATURAL AREA¹

old-growth Douglas-fir - western
hemlock stands growing in a valley
in the southern Washington Cascade
Range.

Wind River Research Natural Area
established on March 28, 1934, to ex-
amine old-growth Douglas-fir (*Pseudotsuga*
sii) - western hemlock (*Tsuga hetero-*
phylla) forests which originally covered many
square miles in western Washington's Cascade
Range. The 478-ha. (1,180 acre) tract is lo-
cated in Skamania County, Washington, and
administered by the Wind River Ranger
Station (Carson, Washington), Gifford Pin-
chot National Forest. It is also a part of the
Wind River Experimental Forest, a 1,330 ha.
(3,280-acre) area maintained by the Pacific
Forest and Range Experiment
Station for research and demonstration of
management techniques in the Douglas-fir
ecosystem (U.S. Forest Service 1961b). The tract
includes portions of sections 8, 17, 20, and
34 N., R. 7 E., Willamette meridian
(WR-1). Boundaries are based on legal
descriptions except for the southern boundary
on section 20 which is 90 m. (300 ft.) north of
Trout Creek. The natural area
is 45° 49' N. latitude and 121° 58' W.
longitude.

the south via the Columbia River (U.S. Hi-
way 830), Carson, and the Wind River val-
ley following Forest Highway 30 and Forest
Road N411 to Hemlock Ranger Station (Wind
River Ranger District). Just west of the ra-
nger station turn onto Forest Road N417, which
crosses the southwestern corner of the nat-
ural area about 3.2 km. (2 miles) from the sta-
tion (fig. WR-1). The eastern edge of the nat-
ural area can be reached and is crossed by For-
est Road N400, a low standard road which lies
north from Forest Road N417 about 0.8
(0.5 mile) west of the ranger station.

A trail crosses section 20 and follows the
northern edge of section 21, connecting For-
est Roads N417 and N400 and providing
access to the southern half of the natural area.
The northern half is probably easiest to reach
by cross-country travel from Forest Road
N417 which climbs the eastern slopes of Trout
Creek Hill just west of the natural area bound-
ary.

The nearest commercial accommodations
are in Stevenson, about 24 km. (15 miles)
away. However, there are several improved
forest camps in adjacent portions of the Wind
River valley.

ENVIRONMENT

The natural area occupies gently sloping
undulating topography on the lower slopes of
the Wind River valley and Trout Creek Hill.
An extinct shield volcano (fig. WR-1). Topog-
raphy is somewhat steeper in the northwest

00 ft.)
 Bedrock in the natural area consists almost entirely of olivine basalts of Pleistocene-recent age (Wise 1970). These materials are part of the flows which originated on Trout Creek Hill. Wise (1970) has provided some geological information on these basalts. Trout Creek Hill is surmounted by two cinder cones, and bedrock in the natural area is rarely encountered due to various surface deposits. Most of these, if not all, are composed of volcanic ejecta of unknown sources. On the lower slopes of Bunker Hill, at the extreme eastern edge of the natural area, are occupied by Eocene to Oligocene andesitic and rhyodacitic pyroclastic rocks belonging to the Ohanapecosh Formation (Wise 1970).

A cool, moist climate prevails. Precipitation is seasonal, peaking during winter months and reaching lowest levels during the summer. Summer drought periods of 2 months' duration have been recorded (Steele 1952). Much of the winter precipitation occurs as snow, and at least some snow cover typically blankets the natural area during most of the winter. The following climatic data are for the Hemlock Ranger Station located about 10 km. (2 miles) southeast of the natural area and are probably quite representative of conditions there (Wind River Station in U.S. Weather Bureau 1965); additional climatic data are summarized by Steele (1952):

mean annual temperature	8.7°C. (47.8°F.)
mean January temperature	0.0°C. (32.0°F.)
mean July temperature	17.5°C. (63.5°F.)
mean January minimum temperature	-3.7°C. (25.3°F.)
mean July maximum temperature	26.9°C. (80.5°F.)
average annual precipitation	...	2,528 mm. (99.51 in.)
precipitation through August	119 mm. (4.67 in.)
average annual snowfall	233 cm. (91.7 in.)

Brunns Acides great soil group. A profile located in flat topography in the part of the natural area is as follows:

01	4 to 3 cm.	Undecomposed matter; pH 5.0.
02	3 to 0 cm.	Mainly decomposed recognizable matter; pH 5.0.
A1	0 to 25 cm.	Dark brown silty loam; granular texture; abundant roots; pH 5.0.
A3	25 to 50	Brown silty loam; weakly subangular texture; abundant roots; pH 5.0.
B21	50 to 74 cm.	Dark yellow sandy loam; medium blocky structure; pH 6.3.
IIB22	74 to 81 cm.	Strong brownish brown loam; massive texture; common sized, weathered pumice; pH 5.0.
IIIB23	81 to 132 cm.	Dark yellow loam; strong angular blocky texture; common weathered, yellowish pumice; pH 5.0.
IIIB24	132 to 170 cm.	Yellowish sand; weakly subangular texture; occasionally very-weathered, el-sized pumice; pH 5.0.
IIIB3	170 to 190 cm. +	Dark gray loamy sand; common, silty, weathered, pumice; a dish brown

neral, soils become darker, and the podzolic from east to the west, and over to higher elevations within the area.

A convenience all 478 ha. (1,180 acres) of natural area can be classified as SAF cover (80, Douglas-Fir - Western Hemlock (American Foresters 1954), and Fir's (1964) Type 2, Cedar - Hemlock - Douglas Fir Forest. Localized areas could only be typed as SAF type 224, Western Hemlock. Some of the swamplier ground on the eastern edge of the natural area has substantial amounts of western redcedar (*Thuja*), and there is some acreage of open land and marsh. The natural area is located in the *Tsuga heterophylla* Zone of Frank and Dyrness (1969). However, it contains a rising number of subalpine or montane (*Amabilis* Zone) elements, considering the low elevation it occupies; e.g., an abundance of Pacific silver fir (*Abies amabilis*), a small noble fir (*Abies procera*), and the *Rhytidiopsis robusta*. This may be partly due to valley microclimatic influences. Most of the natural area is occupied by old-growth forest stands but there are some areas of younger age classes (fig. WR-1). A notable is the approximately 70-year old Douglas-fir stand located south of Forest Road in section 20. This stand dates from the Yacolt Burn. Two small areas along the northeastern boundary of the natural area were accidentally logged when the adjacent, private, forest lands were cut 50 to 60 years ago; they are now occupied by a second-growth Douglas-fir stand.

Three species found within the natural area are Douglas-fir, western hemlock, western

story position. Western redcedar is most common in the eastern extremity of the natural area.

Stand growth and mortality in the natural area have been studied since 1947 (table WR-1). Site productivity is only moderate, an average Douglas-fir site index of 130 (class III) indicating Douglas-fir dominance should average 40 m. (130 ft.) in height at the index age of 100 years. The 350-year-old stand contains a total stand volume of 96,880 cu. m. per ha. (96,880 bd. ft. per acre) and is making considerable annual growth despite its advanced age (table WR-1). Most growth is offset by mortality in the Douglas-fir and western white pine, however. A epidemic of Douglas-fir bark beetles (*Dendroctonus pseudotsugae*), which climaxed during 1951 to 1953, and windthrow (fig. WR-2) have been the chief causes of mortality in Douglas-fir. Mountain pine beetles (*Dendroctonus monticolae*) and white pine blister beetle (*Parasitium ribicola*) have practically eliminated the western white pine. Some western hemlock have been lost to windthrow and mistletoe (*Arceuthobium campylopodum*) infections.

Forest stands in the natural area are progressing toward a climax of western hemlock and Pacific silver fir, a process accelerated by heavy mortality in the Douglas-fir overstory. Although Pacific silver fir is below its elevational range as a climax species throughout most of the Cascade Range, it is reproduced in stands Pacific silver fir seedlings and saplings are as abundant as, or more so than, the western hemlock. The growth and mortality data (table WR-1) further illustrate the process of stand succession with heavy losses of Douglas-fir and western white pine from the

b layer is typified by *Berberis nervosa*, *Linnaea parvifolium*, *Gaultheria shallon*, *Linnaea membranaceum*, *Rubus ursinus*, and in local areas, *Rhododendron macrocarpum*. Conspicuous herbs include *Clinopogon uniflora*, *Achlys triphylla*, *Pteridium aquilinum*, *Xerophyllum tenax*, *Linnaea borealis*, *Trillium ovatum*, *Anemone deltoidea*, *Thalictrum umbellata*, and *C. menziesii*. Mosses are *Eurhynchium oreganum*, *Leucophaea megaptillum*, and *Rhytidiopsis robusta*. Moisture habitats have greater coverage of herbaceous species and less fertile, drier habitats greater amounts of ericads, such as *Gaultheria shallon* and *Xerophyllum tenax*. Two stands sampled during a study of forest communities in the southern Washington Cascade Range were assigned to an *Amabilis/Gaultheria shallon* Association (Franklin 1966); at least a part of the area could be characterized by a *Tsuga heterophylla/Acer circinatum* - *Berberis nervosa* association.

Mammals believed to utilize the natural area as residents or transients are listed in table WR-2. Some minor hunting of larger game animals occurs within the natural area. Shelford (1963) observed that ants (*Formica subsericea melanotica*) were the commonest insects on animal paths. Tenebrionid beetles (*Iphidius serratus*) and tiger beetle larvae were also in evidence. He also collected western toads (*Bufo boreas*) and tailed frogs (*Ascaphus truei*) from the natural area.

There are no permanent streams within the natural area. The ponds and swamps at the foot of Bunker Hill provide the major areas of aquatic and semiaquatic habitat (fig. WR-2).

HISTORY OF DISTURBANCE

Human disturbance of the natural area is

done right-of-way can be located with difficulty. Recent logging on the south side of the natural area will undoubtedly have some influence, possibly resulting in windthrow within adjacent portions of the natural area.

Natural disturbances appear to be typical of overmature conifer forests in this region, i.e., losses to windthrow and pathogens mentioned earlier. Except for a small area burned in 1902, there is no record for wildfires within the natural area in the last 200 to 300 years.

RESEARCH

Wind River Research Natural Area has a long history of research. Many of the ecological studies of Douglas-fir were carried out here by Leo A. Isaac and his associates (e.g., Isaac 1940, 1943). Included were investigations on natural seedfall, seed storage in the forest floor, seed germination under natural timber, phenology, and moisture conditions of the forest floor. The screens used to collect seed stored in the forest floor in 1940 (Isaac 1940) were located during a reconnaissance of the area in 1969 (fig. WR-2).

The long-term study of tree growth and mortality established in 1947 and continued by Steele and Worthington (1951, 1961) is continuing. This study utilizes four 0.08-ha. (1/5-acre) growth plots, and twenty-seven 0.0016-ha. (1/625-acre) ground vegetation plots systematically located over the natural area. A remeasurement of the growth plots was completed in 1971 and provides 24 years of record.

Numerous observations have been made within the natural area by visiting naturalists and forest managers.

of which is similar in forest type and
ment. The possibility exists of using
parts of the experimental forest for
involving destructive sampling or
ulation and using the natural area as
site.

WOLF CREEK RESEARCH NATURAL AREA¹

Bitterbrush - bunchgrass communities on granitic soils located along the lower east slope of the northern Washington Cascade Range.

The Wolf Creek Research Natural Area was established February 1969 as an example of the bitterbrush (*Purshia tridentata*) - bunchgrass vegetation which occurs on granitic soils at low elevations on the east slope of the Washington Cascades. This vegetation type is important as winter range for big game animals. The 61-ha. (150-acre) tract is located in Okanogan County, Washington, and is administered by the Winthrop Ranger District (Winthrop, Washington), Okanogan National Forest. It is rectangular in shape; the east, north, and west edges are partly fenced and follow surveyed section lines and its south edge borders Wolf Creek (fig. WW-1). It is located in the N1/2 of section 1, T. 34 N., R. 20 E., Willamette meridian, at 48°30' N. latitude and 120°15' W. longitude.

ACCESS AND ACCOMMODATIONS

A blacktop and gravel road terminates approximately 0.4 km. (0.25 mile) from the

excellent during summer and often the winter due to limited snow accumulation. Public accommodations are available in Winthrop.

ENVIRONMENT

The Wolf Creek Research Natural Area is located in steep rolling foothills of the Cascade Range. It ranges in elevation from 2,600 to 3,200 ft. Topography varies from gentle and rolling to steep; the ridge top at the north boundary and slopes adjacent to Wolf Creek along the boundary are a series of small benches. The general direction is southerly. Most of the rocks are granite or granodiorite with sedimentary types at lower elevations.

A largely continental climate prevails. Precipitation occurs as snow during cloudy winters. Summers are warm with precipitation, and largely cloudless. 3 months of drought are common. Data from Winthrop, located in a valley (5 miles) to the southeast, are as follows (Weather Bureau 1965):

Mean annual temperature	7.0°
Mean January temperature	-7.0°
Mean July temperature	20.0°
Mean January minimum temperature	-13.1°
Mean July maximum temperature	30.0°
Average annual precipitation	36.8 in.
June through August precipitation	58.0 in.

Estimated areas by major community types are:

Name	Area
<i>Purshia tridentata</i> / <i>Agropyron inerme</i> - <i>Festuca idahoensis</i>	32 ha. (80 acres)
<i>Pinus ponderosa</i> / <i>Purshia tridentata</i> / <i>Festuca idahoensis</i>	16 ha. (40 acres)
<i>Pinus ponderosa</i> - <i>Pseudotsuga menziesii</i> / <i>Symphoricarpos albus</i> / <i>Agropyron inerme</i>	8 ha. (20 acres)

The *Purshia*/*Agropyron* - *Festuca* community type could probably be assigned to Kuchler's (1964) Type 55, Sagebrush Steppe. The *Pinus*/*Purshia*/*Agropyron* community type is assignable to SAF cover type 237, Interior Ponderosa Pine (Society of American Foresters 1954), and Kuchler's Type 10, Ponderosa Shrub Forest. *Pinus* - *Pseudotsuga*/*Symphoricarpos*/*Agropyron* communities could be assigned to SAF forest cover type 214, Ponderosa Pine - Larch - Douglas-Fir, and Kuchler's Type 12, Douglas Fir Forest. The area falls within a forested zone but is largely devoid of trees due to soil factors and slope aspect.

The *Purshia tridentata*/*Agropyron inerme* - *Festuca idahoensis* stands are characteristically dominated by beardless bluebunch wheatgrass (*Agropyron inerme*) and bitterbrush with some Idaho fescue (*Festuca idahoensis*), *Balsamorhiza sigittata*, Sandberg bluegrass (*Poa sandbergii*), and very scattered ponderosa pine (*Pinus ponderosa*) (fig. WW-2). This community type occurs from reasonably level benches to steep southerly slopes, some of which exceed 100 percent. The type can be related to either the *Purshia*/*Festuca* or *Purshia*/*Agropyron* types described by Daubenmire (1970).

The *Pinus ponderosa*/*Purshia tridentata*/*Festuca idahoensis* community is a very open type characterized by a 15 to 25

The forest community of ponderosa pine and Douglas-fir (*Pseudotsuga*) is reasonably representative of plant community potentials. The stands have overstories dominated by ponderosa pine, but tree reproduction is dominated by Douglas-fir. Ground vegetation is dominated by *Symphoricarpos albus* and bunch wheatgrass. Numerous trees are fire-scarred at their base. The basal areas (20.5 sq. m. per hectare) and slow diameter growth suggest limited forest growth potential.

The area is important to mule deer (*Odocoileus hemionus*) as they move off the tract sufficient to spring to prevent grazing damage. Other mammals believed to be residents or transients are listed in WW-1.

HISTORY OF DISTURBANCE

Fire scars on ponderosa pine ground fires periodically burn back to initiation of fire control programs. Lack of dominant old-growth forest area further suggests all ponderosa pine have burned at some time. The volume is present on the ground surface so one should assume it is a fire so one should assume it is a fire.

The Wolf Creek Research Station has been used as livestock range since 1900, primarily for cattle. Heavy grazing occurred in the late 1930's and caused a change of vegetation. However, in 1948, initiation of a grazing season was changed to a time native forage has dried and it is low in livestock palatability. It is damaged by light use. Pro-

logging will be allowed, and timber harvest on adjacent lands should have no impact on the bitterbrush - wheatgrass communities.

RESEARCH

No research is known to be in progress on the Wolf Creek Research Natural Area. The area provides interesting opportunities to study: (1) effects of winter-game use on palatable shrub-bunchgrass vegetation; and (2) biomass productivity in relation to soils and topography in three closely related and intergrading plant communities developed under single macroclimate.

MAPS AND AERIAL PHOTOGRAPHS

No special topographic or geologic maps are available for the natural area which are sufficiently detailed to be useful. Either the District Ranger (Winthrop Ranger District) or Forest Supervisor (Okanogan National Forest, Okanogan, Washington) can provide details on the most recent aerial photo coverage of the area.

Lower right: Ponderosa pine-Douglas-fir community growing on soil and steep slopes probably representing zonal forest community.

APPENDIX I

Examples of Federal Agency Regulations Governing Establishment and Use of Research Natural Areas

Section 251.23 of Title 36, Code of Federal Regulations, which provides the authority for establishment of Research Natural Areas and other experimental areas on National Forest lands, reads as follows:

The Chief of the Forest Service shall establish and permanently record a series of areas on National Forest land to be known as experimental forests or experimental ranges, sufficient in number and size to provide adequately for the research necessary to serve as a basis for the management of forest and range land in each forest region. Also, when appropriate, the Chief shall establish a series of research natural areas, sufficient in number and size to illustrate adequately or typify for research or educational purposes, the important forest and range types in each forest region, as well as other plant communities that have special or unique characteristics of scientific interest and importance. Research Natural Areas will be retained in a virgin or unmodified condition except where measures are required to maintain a plant community which the area is intended to repre-

Section 4063, as of February, follows:

POLICY

The Forest Service will coordinate with other public agencies and such professional organizations as the Conservancy, Society of American Foresters, Society for Range Management, and the Ecological Society of America, to establish and maintain an adequate number and size of research natural areas. The use of research natural areas by scientists inside and outside the Forest Service for certain educational purposes is encouraged.

Research natural areas should include as many as possible of the major, minor, and rare types or other plant communities in good condition. Other forest or range types that have special or unique characteristics of scientific or educational interest, such as outliers of grass or timber, bog associations, or unusual coral reefs, flora may also be set aside. To the extent feasible, animal life also should be maintained in unmodified condition.

SIBILITY

and establishment of research areas on National Forest land may be either in the research or National resource management organization. Supervisors and research project leaders are responsible for proposing establishment, and rangers for protection. The scientific and educational uses made of natural areas by the Forest Service and other scientists may also be a research responsibility.

Research natural areas should be large enough to provide essentially unmodified conditions in their interior portions — usually 100 to 1,000 acres. Exceptions to the usual minimum size should be limited to truly exceptional cases. Seldom can tracts smaller than 100 acres be expected to maintain essentially unmodified conditions unless they are scenic or other areas that are relatively unmodified conditions.

PROTECTION AND MANAGEMENT

Each research natural area must be protected against activities which directly or indirectly affect the natural ecological processes if the area is to be available for observation and research on plant succession, habitat requirements, insect and fungus depredations, geology, biology, phenology, and related subjects. Logging activities and unconforming by domestic livestock are not permitted. The criterion for management of research natural areas is for protection against encroachments.

PROTECTION

through the research natural area, limited posting may be needed to protect the area.

FENCES

Research natural area boundaries need not be fenced unless necessary for protection against livestock or excessive human use.

PUBLICITY

Publicity is generally limited to professional groups at either national, State, or university levels and mainly to inform scientists and educators of the location, vegetation types, and administering agency in order to make the fullest proper use of the research natural areas. Other publicity should be avoided.

PHYSICAL IMPROVEMENTS

Generally speaking no physical improvements such as roads, trails, fences, or buildings should be permitted within a research natural area. Temporary facilities needed for research, such as instrument shelters, may be installed with the approval of the Station Director. Except as essential to fire protection of adjoining lands, no buildings, roads, or trails should be permitted at or on the boundaries of a research natural area.

PROTECTION

Fires within a research natural area should be extinguished as quickly as possible, but not cleanup, fire hazard reduction, or reforestation should be undertaken.

No control of insects or disease should be instituted unless the infestation or infection threatens adjacent forests or will drastically alter the natural ecological processes within the area, for example, white pine blister rust. Insect or disease-killed trees are a part of the natural

ed or capturing
eaten serious impairment of research
ational value. Hunting, fishing, and
; should be prohibited only if the
of game, fish, and furbearers is likely
a scale sufficient to affect the biotic
ities.

SCIENTIFIC AND EDUCATIONAL USE

Forest Service encourages use of re-
natural areas by responsible scientists
cators. Generally the educational use
be at the upper classman or graduate
level. Research on natural areas will
ntially nondestructive in nature. Stud-
require timber felling, seedbed modifi-
or extensive soil excavation should be
the experimental forests and ranges,
ar areas.

use of the fragile character of most
natural areas, cooperative agreements
rmally be prepared between the Forest
and non-Forest Service scientists out-
briefly the mechanics of field research
e limitations thereto. Forest Service
sts should cooperate in the research
er possible in order to derive the
benefit from the work.

Station Directors may authorize such m-
agement practices as are necessary to pres-
some representation of the vegetation
which the natural area was created origin-
including *Ribes* eradication in white
types, control of excessive animal populat-
or prescribed burning or grazing to main-
a grass community. Only tried and rel-
techniques will be used, and then only w-
the vegetative type would otherwise be
without management. The criterion he-
that the management must provide a c-
approximation of the vegetation and the
cesses governing the vegetation than wou-
possible without management. If doubt e-
about the need for vegetation manage-
the reliability of the techniques, then no
should be done. Where management
tices are necessary a portion of natural
should be kept untreated as a "green ch-

MINERAL ENTRY

Research natural areas should be with-
from mineral entry.

APPENDIX II

Index to Research Natural Areas

By Forest Cover and Vegetation Types

h Natural Areas described in this guidebook are indexed here according to r and vegetation types described by the Society of American Foresters (1954) (1964), respectively. The areas are coded here according to the listing provided on the back cover of this report.

Type name	Area in which type exists
Mountain Hemlock - Subalpine Fir <i>Tsuga mertensiana</i> - <i>Abies balsamea</i>	BU, GL, OR, WM
Engelmann Spruce - Subalpine Fir <i>Picea engelmannii</i> - <i>Abies balsamea</i>	GL
Red Fir <i>Abies magnifica</i>	AC, BP
Whitebark Pine <i>Pinus albicarpa</i>	
Interior Douglas Fir <i>Pseudotsuga mucronata</i>	PB
White Fir <i>Abies concolor</i>	AC, BP
Larch - Douglas Fir <i>Larix occidentalis</i> - <i>Pseudotsuga mucronata</i>	BB
Grand Fir - Larch - Douglas Fir <i>Abies grandis</i> - <i>Larix occidentalis</i> - <i>Pseudotsuga mucronata</i>	OD, PE
Ponderosa Pine - Larch - Douglas Fir <i>Pinus ponderosa</i> - <i>Larix occidentalis</i> - <i>Pseudotsuga mucronata</i>	BB, ME, MI, ML, PE, RC, W

223	Sierra Spruce - Western Hemlock <i>Picea sitchensis</i>	NC, TW

APPENDIX III

Index to Research Natural Areas by Tree And Important Range Plant Species

In Natural Areas described in this guidebook are indexed here according to species of selected important range plants present there. The areas are coded here according to the ranges provided in table 1 and on the back cover of this report. Plants are arranged alphabetically by scientific name. A species, when present in small quantities, may be indexed in a Research Natural Area but not appear in the text writeup; indexing is based on field notes and other documentation in such cases.

<i>agrostis rubescens</i> grass	BB, CC, ME, OD, PB, PE, PN, TP
<i>geyeri</i> edge	BB, CC, ME, ML, OD, PB, TP
<i>rossii</i> edge	BJ, GM, MI, PR
<i>auopsis chrysophylla</i> n chinquapin	AC, AS, BP, CH, CO, PO, WH
<i>thus velutinus</i> brush ceanothus	AC, AS, BP, CC, MI, PE, PR, WM
<i>carpus betuloides</i> leaf mountainmahogany	AS
<i>carpus ledifolius</i> leaf mountainmahogany	CC, GM
<i>aeccyparis lawsoniana</i> leaf mountainmahogany	BP, CO, PO

<i>ulula</i>	BU
<i>ifolia</i>	MA, MY, PO, WP
<i>sa</i> ge	RH
<i>cidentalisper</i>	CC, GM, HR, LO, OD
<i>tatagrass</i>	CC, HR, PN, TP
<i>ntalish</i>	BB, ME, MI, ML, OD, PE, RC
<i>ecurrens</i> ar	AC, AS, BP, MI, MY, PE
<i>densiflorus</i>	CO, PO, WH
<i>annii</i> spruce	GL
<i>nsis</i> e	DP, HI, JC, LA, LC, NC, QU, TW
<i>ulis</i> ine	BU
<i>uata</i> ne	BP, WH
<i>rtaine</i>	BB, BJ, GL, PR, SR
<i>rtiana</i>	AC, AS, BP, CO, PO, PR
<i>cola</i> te pine	AC, BA, BP, CF, GL, OR, PO, RC, WM, WR
<i>rosa</i> ine	AC, AS, BB, BJ, CC, GM, LO, ME, MI, ML, OD, PB, PE, PN, PR, RC, TP, WW
<i>gii</i>	CC, GM, ME, ML, PB, PN, RH, TP, WW

<i>Abies balsamifera</i>	HI, JC, LC, MA, ME, MI, ML, MY, NC, NF, OD, O, PB, PE, PI, PO, QU, RC, SR, TW, WH, WM, WP, WR, WW
<i>Abies tridentata</i>	BJ, GM, HR, LO, MI, ML, PR, WW
<i>Abies concolor</i>	BP, PO
<i>Abies chrysolepis</i>	
on live oak	AC, AS, MA, ML, MY, PI, WP
<i>Abies garryana</i>	
on white oak	AS
<i>Abies kelloggii</i>	
California black oak	
<i>Abies sadleriana</i>	
er oak	
<i>Abies raccinifolia</i>	BP
blackberry oak	
<i>Abies sempervirens</i>	WH
West redwood	
<i>Abies hystric</i>	BJ, HR, LO, ME, MI, PR
blebrush squirrel tail	
<i>Abies occidentalis</i>	BJ, MI, ML, PN, PR
Western needlegrass	
<i>Abies brevifolia</i>	AC, AS, BA, BP, CF, CO, LC, MA, NF, PO, RC, V, WR
Chinese yew	BA, CF, HA, HI, JC, LA, LC, MY, NF, PO, QU, V, WR
<i>Abies plicata</i>	
Western redcedar	
<i>Abies heterophylla</i>	AC, BA, BR, BU, CF, CO, DP, HA, HI, JC, LA, I, NC, NF, OR, PO, QU, SR, TW, WH, WM, WR
Western hemlock	
<i>Abies mertensiana</i>	AC, BR, BU, GL, LA, NF, OR, SR, WM
Mountain hemlock	
<i>Abies bellularia californica</i>	MY, PO, WH
California laurel	

APPENDIX IV

Index to Research Natural Areas by Species of Mammals

Species	Area in which type exists
<i>Arctomys a. marsupialis</i>	MA, NC, PI, WP
<i>A. hoyi</i>	BB
<i>A. gibbsii</i>	AC, AS, BP, BR, BU, CF, CH, CO, DP, GL, HA, HI, JC, LA, LC, MA, ME, ML, MY, NC, NF, OR, PE, PI, PO, QU, SR, TW, WH, WM, WP, WR
<i>A. latimanus</i>	AS, BJ, BP, GM
<i>A. parvus</i>	BR, BU, CC, CF, CH, CO, DP, GL, HA, HI, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PE, PI, PO, QU, RC, SR, TW, WH, WM, WR
<i>A. townsendi</i>	AC, BP, BR, BU, DP, HA, JC, LA, LC, MA, MY, NC, NF, PE, PI, QU, TW, WM, WP
<i>A. virgatus</i>	AC, BP, BR, CF, CH, CO, DP, GL, HA, HI, JC, LA, LC, ML, NC, NF, OR, PE, PO, QU, TW, WH, WM
<i>A. reus</i>	BB, BU, LA, LC, ME, NF, WW

<i>edict</i> shrew	
<i>trigonirostris</i> d shrew	
<i>rowbridgii</i> ridge shrew	AC, AS, BP, BR, BU, CF, CH, CO, GL, HA, HI, J, LA, LC, MA, ME, MI, ML, MY, NC, NF, OR, PE, PI, PO, QU, SR, TW, WH, WM, WR
<i>vagrans</i> ring shrew	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, DP, G, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, M, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
<i>yaquinae</i> na shrew	NC
ptera:	
<i>zous pallidus</i> bat	AC, AS, BJ, BP, CC, CH, CO, GL, GM, HR, MA, ME, MY, NC, OD, PB, PI, PO, WH, WP, WW
<i>cus fuscus</i> rown bat	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, I, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
<i>myotis noctivagans</i> -haired bat	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, I, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
<i>rus borealis</i> at	AC, AS, BJ, BP, BR, CH, CO, GL, GM, HA, HR, MA, ME, MI, MY, NC, OR, PE, PI, PO, PR, WM, WP, WW
<i>rus cinereus</i> y bat	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
<i>is californicus</i> ornia myotis	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW

myotis	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, DP, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, MY, NC, NF, OD, OR, PB, PE, PI, PO, PR, QU, RC, RH, SR, TW, WH, WM, WP, WR, WW LC, NF
gus myotis	AC, AS, BB, BJ, BR, BU, CC, CF, CH, CO, DP, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
atus myotis	CC, HR, OD, PB, PN, RC, TP
nodes tis	AC, AS, BJ, BP, BR, CC, CH, CO, GL, GM, HR, MA, ME, MI, MY, NC, OD, OR, PB, PE, PI, PO, PR, RC, WH, WM, WP, WW
s myotis	AC, AS, BJ, BP, BR, BU, CC, CF, CH, CO, DP, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, MY, NC, NF, OD, OR, PB, PE, PI, PO, PR, QU, RC, RH, SR, TW, WH, WM, WP, WR, WW
ensis s	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, DP, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
hesperus strel	CC, HR, OD, PB, PN, TP
nsendi g-eared bat	AC, AS, BJ, BP, BR, CC, CF, CH, CO, DP, GL, GM, HA, HI, HR, JC, LA, LC, MA, ME, MI, ML, MY, NC, NF, OD, OR, PB, PE, PI, PN, PO, PR, QU, RC, RH, SR, TP, TW, WH, WM, WP, WR, WW
siliensis e-tailed bat	AS, WH
i: canus re	AC, AS, BB, BP, BR, BU, CC, CF, CH, CO, DP, GL, HA, HI, JC, LA, LC, ME, MI, ML, NC, NF, OD,

rabbit	BB, BJ, GM, HR, ME, PB, PN, PR, RC, TP, WW
<i>gus nuttalli</i>	
ain cottontail	
ia:	
<i>mtia rufa</i>	AC, AS, BP, BR, BU, CF, CH, CO, DP, GL, HA, I, JC, LA, LC, ML, MY, NC, NF, OR, PE, PO, QU, SR, TW, WH, WM, WR
ain beaver	BR, CH, CO, NC, PO, WH, WM
<i>mus albipes</i>	
footed vole	
<i>mus longicaudus</i>	AC, BP, BR, CH, CO, GL, MA, NC, OR, PE, PO, WH, WM
ee vole	
<i>e canadensis</i>	BU, CC, CF, CH, CO, DP, GL, HA, HI, JC, LA, I, MY, NF, OD, PE, PO, PR, QU, RC, TW, WR, WW
r	
<i>ionomys californicus</i>	AC, BP, BR, CH, CO, GL, MI, ML, MY, NC, PE, PO, WH, WM
rnia red-backed vole	
<i>ionomys gapperi</i>	BB, BU, CC, CF, DP, HA, HI, JC, LA, LC, ME, OD, PB, QU, RC, SR, TW, WR, WW
er red-backed vole	
<i>lomys heermanni</i>	
mann kangaroo rat	
<i>lomys ordi</i>	HR
kangaroo rat	
<i>izon dorsatum</i>	AC, AS, BB, BJ, BP, BR, BU, CC, CF, CH, CO, GM, HR, ME, MI, ML, NC, NF, OD, OR, PB, P, PN, PO, PR, RC, SR, TP, WH, WM, WR, WW
upine	
<i>mias amoenus</i>	AC, AS, BB, BJ, BP, BR, BU, CC, GL, GM, HI, ME, MI, ML, NF, OD, OR, PB, PE, PN, PR, RC, SR, TP, WM, WW
w-pine chipmunk	
<i>mias minimus</i>	HR, RH
t chipmunk	
<i>mias ruficaudus</i>	BB

REQUEST FOR NOTIFICATION
CONCERNING SUPPLEMENTS TO OR REVISIONS OF
FEDERAL RESEARCH NATURAL AREAS IN OREGON AND WASHINGTON
A GUIDEBOOK FOR SCIENTISTS AND EDUCATORS

I wish to be informed of additions to or revisions of the material in this guidebook please
fill out the attached form and mail it to the address shown.

Director
Pacific Northwest Forest and
Range Experiment Station
P.O. Box 3141
Portland, OR 97208
U.S.A.

I would like to be informed of any supplements to or revisions of this Research Natural Area
Guidebook which you issue.

(Name)

ESTABLISHED RESEARCH NATURAL AREAS ON FEDERAL LAND OREGON AND WASHINGTON

Name	State	Principal Features	Admin. Agency ¹
tt Creek	OR	Southwestern Oregon mixed conifers, especially sugar pine	FS
and	OR	Pacific ponderosa pine, also mixed with Douglas-fir	FS
y	OR	Douglas-fir, western hemlock	FS
l Basin	WA	Ponderosa pine, larch, Douglas-fir	BSFW
ay	OR	Ponderosa and lodgepole pine on pumice	FS
er Spruce	OR	Brewer spruce	BLM
Run	OR	True firs, western hemlock	FS
er Creek	WA	True firs, subalpine meadows, and avalanche tracks	NPS
on Creek	OR	Ponderosa pine	FS
r Flats	WA	Western redcedar, Douglas-fir	FS
ry Creek	OR	Coast Ranges Douglas-fir	BLM
ille River Falls	OR	Port-Orford-cedar	FS
ond Point	WA	Sitka spruce-western hemlock	BSFW
Lake Bog	OR	Bog communities and flora	FS
low Mountain	OR	Ponderosa pine	FS
s Creek	WA	Pacific silver fir-western hemlock forests	NPS
y Creek	WA	Western hemlock	NPS
e Ridge	OR	Western juniper	BLM
on Creek	WA	Douglas-fir	NPS
Twentytwo	WA	Western redcedar-western hemlock	FS
Creek	WA	Western hemlock	FS
Forest	OR	Ponderosa pine stand isolated in steppe	BLM
e Knoll	OR	Bigleaf maple	BSFW
s Table	WA	Ponderosa pine	FS
ius	OR	Ponderosa pine	FS
Creek	OR	Oregon white oak, conifers, and steppe	FS
e Island	OR	California laurel	BLM
owin Crest	OR	Sitka spruce-western hemlock	FS
a Fork Nooksack	WA	Douglas-fir, western hemlock	FS
o Divide	OR	Ponderosa pine, grand fir	FS
e Ridge	OR	Mountain meadows and flora	FS
a Bunchgrass	WA	Bluebunch wheatgrass	FS
a M. Robinson	OR	Douglas-fir, ponderosa pine	FS
n Butte	OR	Oregon white oak	BSFW
Creek	WA	Ponderosa pine	BSFW
Orford Cedar	OR	Port-Orford-cedar and Douglas-fir forests	FS
le Falls	OR	Ponderosa and lodgepole pine	FS
ult	WA	Western hemlock, Sitka spruce	FS
ow Creek	WA	Eastern Oregon mixed conifer	FS
esnaque Hills	WA	Arid shrub-steppe (sagebrush)	AEC
s Rocks	WA	Pacific silver fir	FS
